I feel we are not doing justice to our cause by harping so much on the material angle. If we insist on conditions which preserve this relationship everything else follows automatically, for all conditions which will or may turn us into Civil Servants would have to be withdrawn. Is it too late, even now, for a big publicity effort directed especially to the general public and explaining and stressing this most vital point?—I am, etc.,

Nairobi, Kenya.

KEITH DUFF.

A Clear Reply

SIR,—Already one is being asked, unofficially of course, "How do we stand with reference to the new scheme and with you, Doctor?" What is one to say, and should not you, Sir, give a lead so that we may speak with one voice? Let us be clear and loud in our reply, which one would suggest should be in the following terms: We cannot say anything definite, but if the scheme is modified, as we hope it will be, to remove all our objections, then there should be no difficulty.

Is this enough, or should one explain further? And will this be enough when the patient is advised by the Ministry to ask his doctor whether or no he is coming into the scheme? No evasive action will then suffice with a public which has been led to believe that the Act is coming into force on July 5: whether the doctors agree or not.

Whether we like the method or not we shall require to adopt the method of the present Government and put our position clearly to the public by poster, leaflet, and radio. At least every practitioner should have a card which he can place in his waiting-room which states clearly his position regarding July 5.—I am, etc.,

London, N.6

W. LEES TEMPLETON.

Implementing the Vote

SIR,—It is surely time for those of us who voted No in the plebiscite to devise means for implementing our vote. Which of us is serenely happy at the prospect of disposing of the Minister's contract or deed of acceptance when the time comes? Is there not some element of doubt in our minds about the other fellow? We all have much at stake and we shall need a lot of reassurance. We do not like the scheme, but we want to remain solvent. There is to be a central fund, but we are not beggars. We may despise the timid, but the timid may well outnumber the fearless. I submit this proposition to all who voted No—to the fearless and the timid, counting myself among the latter. I should add that it is not my own idea, having been outlined originally by a colleague at a meeting of the local branch of the B.M.A.

The suggestion is that the B.M.A. should act as agent for the individual practitioners. Each practitioner should forward the contract or deed of acceptance or whatever may be the instrument selected by the Minister to the B.M.A. with instructions such as the following:

I am reluctant to enter this scheme but I am not prepared to forfeit my capital and possibly the greater part of my income for an indefinite period without the assurance that the majority of the profession is prepared to do likewise. If you are satisfied that such a clear majority is attained, I wish to be associated with it. But if it is not attained, I wish to accept service in the scheme, with regret. You should inform the Minister or his representatives accordingly.

The word "majority" should be clearly defined beforehand, and I have never seen any quarrel with the original figure for such a majority, which was, I believe, 63%. I trust that some such arrangement may be organized and adequately advertised before any one of us is faced with that contract paper with only a Thomas as counsellor.—I am, etc.,

Loughborough, Leics.

R. E. RAINEY.

Foresight

SIR,—Would you allow me to say with how much pleasure (not unminged with a little pain, be it said) I read your correspondence in these days? The pleasure goes without any more stressing; the pain is due to the almost contemptuous silence which met my letter in your columns (*Supplement*, Dec. 2, 1944, p. 134), when not a pen was lifted in support of the views expressed in it. The subject was the Coalition Government's

White Paper. I imagine that one of the reasons why I suffered neglect was that most of your present-day correspondents were still in the karyokinetic stages of their medico-political development. I am glad to think they have now passed the early stages of dentition, for some of them *can bite!* But, Sir, why ask for more than the fundamental requirements enumerated in the White Paper above quoted?—I am, etc.,

London, S.W.3.

A. R. EATES.

Assistant Dispensers in N.H.S.

SIR,—I am from time to time asked what is to be the position of assistant dispensers under the new Health Service, and shall be grateful if you will allow me, through your columns, to clarify the position in so far as this is at present possible. The Act lays down that "nothing in this Act shall interfere with the rights and privileges conferred by the Apothecaries Act, 1815, upon any person qualified by that Act to act as an assistant to any apothecary in compounding and dispensing medicines." With the taking over of the hospitals it is anticipated that the staffs will continue in their existing posts, and it is thought that many health centres will employ holders of the Assistant's Certificate. It cannot yet be known how many doctors will continue to dispense their own medicines, but at the present time the demand for assistant dispensers far exceeds the supply.—I am, etc.,

The Worshipful Society of Apothecaries
of London.

ERNEST BUSBY,
Clerk.

Iron in Anaemia

SIR,—With reference to the question and answer on iron in anaemia (March 27, p. 625), we agree from our own experience that there is no advantage in adding manganese or other trace elements. Iron seems to be specific in this disease.

We have been concerned for a long time with the problem of refractory microcytic hypochromic anaemias. Even when due allowance is made for complications such as neoplasm, infection, and continued haemorrhage, and when concurrent deficiencies of vitamins, thyroid, etc., have been corrected, they have formed a not inconsiderable proportion of the total. Such patients appear unable to absorb adequate quantities of iron, while an additional group of patients are unable to tolerate iron preparation when given orally. In a much larger number of cases the response to oral iron falls short of expectations.

The problem, therefore, is one of introducing sufficient iron into the body in a form free from the complications of local pain and toxic reactions. Once introduced, iron-deficiency anaemia appears to utilize it quantitatively. We have made many trials of different types of iron compounds parenterally, both by the intramuscular and the intravenous routes, but all the intramuscular preparations tried proved to be too painful. On the other hand an intravenous iron-sucrose complex, similar to the saccharated iron used by J. A. Nissim (*Lancet*, 1947, 2, 49), but having constant therapeutic and chemical characteristics in routine sterilization, has given entirely satisfactory results with freedom from reactions in the day-to-day out-patient treatment of 55 cases of iron-deficiency anaemias during the past twelve months. It has also proved invaluable in the experimental study of iron metabolism.

The clinical results and studies on iron metabolism, using this complex, are now in preparation for publication. Using this preparation the treatment of the average patient with iron-deficiency anaemia can be completed in 10 out-patient visits without fear of reactions, provided that a simple system of increasing the dosage is adopted. The injections present no special difficulties after a short initial experience, and no follow-on venous lamage is ordinarily required. Many of the clinical results are as dramatic as the response of pernicious anaemia in relapse to full doses of parenteral liver. In all cases of iron-deficiency anaemia the anaemia was relieved fully.—We are, etc.,

H. G. B. SLACK,
JOHN F. WILKINSON.

Manchester.

Human Chorionic Gonadotrophin

SIR,—In the annotation on this subject (April 3, p. 650) attention is drawn to observations of Brown and Bradburg (*Amer. J. Obstet. Gynec.*, 1947, 53, 749) of the effect of human chorionic gonadotrophin on the menstrual cycle of

women, and the conclusion is reached that their findings strengthen the suggestion that chronic gonadotrophin prolongs the activity of a pre-existing and functioning corpus luteum, but does not by itself induce ovulation or initiate luteal activity. The further inference was drawn "that it should be used when it is desired to enhance already established but deficient luteal activity. . . ."

That it would appear to be unwise to accept without considerable reserve either of these conclusions may be deduced from the findings in two cases of hydatidiform mole which I have recently investigated. The Friedman test was positive at dilutions of 1 in 10 and 1 in 100 respectively (10 ml. urine being the standard quantity injected), indicating the presence of considerable quantities of chorionic gonadotrophin (not less than 20,000 and 200,000 I.U. per litre respectively), but in both cases the urinary pregnanediol excretion was nil when estimated on five occasions. If one accepts the urinary pregnanediol level as reflecting the blood progesterone concentration, the inescapable conclusion is that in these cases abnormally large amounts of chorionic gonadotrophin were incapable of maintaining the activity—and it may be wise to emphasize activity rather than morphology—of established corpora lutea.

There is a further inference to be drawn from these observations, namely that the placental tissue responsible for the elaboration of chorionic gonadotrophin cannot be the same as that which, in the second and third trimesters of pregnancy, secretes progesterone.—I am, etc.,

London, W.C.1

G. I. M. SWYER.

Posterior Pituitary and Labour

SIR,—Dr. Mavis Gunther's letter (March 20, p. 567) recording her observations on the escape of milk during the contractions of labour are most interesting. Though pregnancy should inhibit the lactating processes, lactation does continue in spite of the large amount of oestrogens being produced. But it is usual to find that if this is the case prolactin has continued to be secreted because of suckling. It would be therefore interesting to know when this terminated in actual fact.

Many mothers even though gravid continue for various reasons to suckle till term, and therefore, in theory, milk should in these cases be present in the breasts at the onset of labour. The myo-epithelium—the basket cells that surround the alveoli—because of their contractibility, and provoked by the posterior pituitary extract, can be responsible for the expulsion of the contained milk, and this is what Dr. Gunther observed. The visual demonstration of this expulsion coinciding with each uterine contraction, and the knowledge that the former is due to posterior pituitary extract, is highly suggestive that the uterine contractions were identically produced.—I am, etc.,

London, W.1.

JOHN SOPHIAN.

BAL and Lead Poisoning

SIR,—The article by Dr. N. R. W. Simpson (March 20, p. 545) adds another link to the lengthening chain of evidence that 2:3 dimercaptopropanol is effective in the treatment of chronic gold poisoning. The curative action of BAL on the toxic effects of gold in man runs counter to the experimental findings in acute toxicity studies in mice. Graham and Hood (1947) found that BAL, 40 mg. per kg., given intraperitoneally to groups of white mice increased the lethality of sodium aurothiomalate also given intraperitoneally immediately before the BAL. The mode of action of BAL on acute gold poisoning in animals and chronic gold poisoning in man is obviously different.

Similarly Braun, Lusky, and Calvery (1946) working with rabbits, and Graham and Hood (1947) working with mice, have shown that BAL has a deleterious effect on animals acutely poisoned with lead. It does not follow that BAL will be ineffective in acute or chronic lead poisoning in man. This point should be tested clinically as soon as possible, since the treatment of lead poisoning at present is not entirely satisfactory.—I am, etc.,

Glasgow.

Disk Lesions and Osteopathy

SIR.—Dr. G. Macdonald's partisan letter (April 3, p. 663) really cannot be allowed to stand unchallenged. A. T. Still (the founder of osteopathy) postulated that *all* diseases arose from pressure on arteries and nerves as the result of vertebral displacements. If medical research has led to the recognition of spinal disk protrusion, and if this is now claimed as the vindication of osteopathy, it must prove the opposite of Dr. Macdonald's contention. Surely it shows that the whole of osteopathic doctrine, except in that small particular, is false.—I am, etc.,

London, W.1.

JAMES H. CYRIAX.

Intervertebral Disk Lesions

SIR.—I was interested in the letter by Dr. J. Donaldson Craig and Mr. A. W. Lipmann-Kessel (March 20, p. 570) concerning sciatica produced by prolapsed intervertebral disks. They state that the pain produced by stimulating the fifth lumbar inter-spinous ligament is clinically and subjectively indistinguishable from that occurring spontaneously in an L5-S1 disk lesion, and also that sciatic pain might be regarded as a deep segmental pain due to joint disturbance.

I would suggest at the present time that we are in danger of considering that every case of sciatica must be caused by direct pressure of a displaced disk on a nerve root, thus causing direct pressure pain. It is true that in some cases where operative exploration is undertaken for sciatica the surgeon fails to see a disk prolapse, and yet to his pleasure the patient appears cured, at any rate for some time, of the distressing sciatic pain. Possibly the mere exposure of the dural sac and the traction of it in exploring the disks is sufficient to tear down adhesions in that area. Recently I dealt with a case that illustrates well the points brought out by Dr. Donaldson Craig and Mr. Lipmann-Kessel in their letter.

A well-built young man, aged 28, was referred to me at Fleet Hospital, Hampshire, by Dr. Sharkey on account of pain in the back and sciatica of five months' duration, following a fall on to his back at football. Diagnosing a prolapsed disk causing moderate pressure, for a further four months I carried out the so-called old-fashioned treatments for sciatica—namely, diathermy applied to the back and leg, stretching of the nerve, and manipulation of the spine. Immobilization both in bed and in a plaster spinal jacket was tried, all to no effect. Finally I decided to explore the spinal cord. After removing the ligamentum flavum between the 4th and 5th laminae, and the 5th lamina, I found no prolapse of the 4th disk. On proceeding, however, to remove the ligamentum flavum from the 5th lamina to the 1st sacral, with a view to removing the sacral lamina and exploring the 5th disk, I found that there was a local adhesion of the posterior aspect of the dura to one point on the flaval ligament, just at the level of the sacral lamina. On passing a hook around the adhesion to determine its size and desirability of cutting, it was noted that traction on it produced contractions of the posterior leg muscles. Further investigation showed that one of the roots of the cord equina was also adherent in the adhesion. The adhesion was freed from the ligament and resected off the underlying root, and the dural hole carefully sutured. No prolapse of the 5th disk was found. To my joy the next day the patient reported that he had completely lost his sciatic pain, and after a normal convalescence he returned to his job as a schoolteacher, standing, and riding a bicycle to school. He has had no return of backache or sciatica.

Such a case would bear out some of the early views held that backache and sciatica may be caused by adhesions of the soft tissues to the cord and roots rather than always being due to disk pressure, which appears to be the modern trend of thought.—I am, etc.,

London, W.1.

G. O. TIPPETT.

Bone Conduction in Otosclerosis

SIR.—I would like to refer to the letter by Mr. W. H. B. Magauran (March 20, p. 569) concerning air and bone conduction tests in otosclerosis. It has been known for some time now that improvement of hearing by both air and bone conduction occurs in the unoperated ear in a certain number of cases—but not by any means all—following the fenestration operation, but the improvement is never permanent. In fact in over 500

fenestrations I have not one case of sustained improvement by air or bone conduction over six months in the unoperated ear, though improvement be fully maintained in the operated ear.

I feel bound to confess, my amazement that anyone practising the fenestration operation to-day should rely upon inaccurate tuning-fork tests—and the one fork of the least importance at that, namely 256—for selection of suitable cases. Mr. Magauran states that "bone conduction . . . was found to be lengthened by a few seconds and to be reduced by about 50% on the left mastoid bone." I cannot help feeling that if adequate audiometric analysis had been carried out before the operation both ears may have been found suitable for the operation and the patient would not have had to rely on the result of the first operation to determine whether the second ear would respond to the fenestration operation also.

I could not agree more with Mr. R. Scott Stevenson's letter (March 27, p. 618) in regard to the need for a careful, sober, and dispassionate estimation of the results of the fenestration operation for otosclerosis. I would like to reiterate the plea that I made in the *Post-Graduate Medical Journal* (November, 1947) for the institution of most careful records of the pre-operative examination, details of the actual operative technique, and post-operative records at intervals of one month, three months, six months, and then yearly for ten years. In addition to these records a questionnaire should be answered yearly by the patients regarding the state of the result from their own point of view.

It is advisable that this operation should not be performed sporadically, but only by those who are willing to take time and pains necessary to develop an irreproachable operative technique, and who will undertake the complete after-treatment either by themselves or by an assistant specially trained for this purpose. Those otologists regularly practising this operation under these conditions should in my opinion compare their results from time to time, especially in relation to the technique of the operation, for it is beyond doubt that those employing the best technique obtain the best results. It is inexpedient to come to conclusions of the value of the fenestration operation based on the results of those only occasionally performing it.—I am, etc.,

London, W.1

E. R. GARNETT PASSE.

SIR.—Mr. W. H. B. Magauran (March 20, p. 569) can only have seen an abstract of the paper which I read to the Royal Academy of Medicine in Ireland on "Bone Conduction in Otosclerosis," which no doubt accounts for a misconception about one of its main points.

In a study of cases before and after the fenestration operation I showed that, after omitting those cases in which pre-operative masked bone conduction was normal and those cases in which no improvement in air conduction took place, the acuity of hearing for masked bone conduction in the operated ear was increased in 90% of cases. There was no alteration of masked bone conduction in the unoperated ear, and in fact the unoperated ears were used as controls to show that the alteration of bone conduction in the operated ears was a genuine improvement. Mr. Magauran's finding of a "considerable lengthening of bone conduction in the unoperated ear" is directly contrary to my findings, and strongly suggests that the operated ear was inadequately masked during the test. Without adequate masking of the untested ear, bone-conduction tests in otosclerosis may be quite misleading. I have never seen the hearing of the unoperated ear altered in any way, either for air or bone conduction; and indeed it is inconceivable that an operation on one ear could affect the working of the opposite one. Such a result can only be explained as an error in testing, either on the part of the patient or the examiner.

There is one further point. In assessing the suitability of a case of otosclerosis for the fenestration operation, bone-conduction tests with a 256 tuning fork are quite valueless. These tests must be performed at 512, 1024, and 2048 cycles per second. Normal bone conduction is often found at 256, when there is severe loss in the higher frequencies. Furthermore, neither tuning forks nor conversation voice tests can be used for quantitative estimation of the degree of deafness without introducing errors so large as to make the results of little value. If the results are to be expressed quantitatively audiometric measurement must be used.—I am, etc.,

Dublin.

R. R. WOODS.

A SINGLE* SUPPLEMENT FOR SAFER PREGNANCY

Pregnavite

CLINICAL USES

To improve the nutritional state where circumstances prevent consumption of all the protective foods required: to prevent hypochromic anaemia. Indications in the history of previous pregnancies: toxæmia, previous premature births, inability to breast feed, dental caries.

* The recommended daily dose provides: vitamin A 2,000 i.u., vitamin D 300 i.u., vitamin B₁ 0.6 mg., vitamin C 20 mg., vitamin E 1 mg., nicotinamide 25 mg., calcium 160 mg., iron 68 mg., iodine, manganese, copper, not less than 10 p.p.m. each.

Vitamins Limited
Upper Mall, London, W.6

A SINGLE* SUPPLEMENT FOR MULTIPLE DEFICIENCIES

Complevite

CLINICAL USES

As a general dietary supplement: in restricted diets, gastro-intestinal diseases: in fluid and light diets: in low fat and other special diets: hyperthyroidism and other states with raised B.M.R.: in chronic infections: throughout convalescence. Also for replacing other preparations of more limited application where full therapeutic doses of the vitamins are not required.

* The recommended adult daily dose provides: vitamin A 2,000 i.u., vitamin D 300 i.u., vitamin B₁ 0.6 mg., vitamin C 20 mg., calcium 160 mg., iron 68 mg., iodine, manganese, copper, not less than 10 p.p.m. each.

Vitamins Limited
Upper Mall, London, W.6

Crookes Halibut Oil

in *new*, palatable, miscible
form for bottle-fed
infants

The richest sources of vitamins A and D — the livers of fish — have always had the disadvantages of strong taste and difficulty of mixing with milk. Crookes have now developed their new Halibut Oil *Emulsion* for Infants to overcome these difficulties.

This new Emulsion, which is basically the highly potent Crookes Halibut Oil, mixes immediately with milk and is agreeable to take. Three drops in the infant's feed, for only 4 of the daily feeds, provides 3000 I.U. of vitamin A and 800 I.U. of vitamin D.

CROOKES HALIBUT OIL EMULSION FOR INFANTS

Obtainable only from Chemists — 3'6d a bottle.

Literature available upon request.

Rutin in Capillary fragility

Rutin is a crystalline glycoside obtained from the leaves and flowers of buckwheat. Recent reports attribute to Rutin the property of reducing capillary fragility when this is abnormally raised.

In our research laboratories a limited quantity has been isolated from buckwheat grown in this country and is available in the form of tablets.

Rutin A & H is suggested for administration in haemorrhagic conditions due to increased capillary fragility or permeability, especially when this condition is associated with hypertension, nutritional deficiency or toxic effects of drugs.

Literature and price on application.

Prevention of Post-operative Thrombosis

R.—I should like to make comment on certain points in Hamilton Bailey's article (March 27, p. 594). In that article emphasizes the importance of early detection of phlebotomosis—importance which cannot be overstressed. He proceeds to remark that the goal of prevention of phlebotomosis cannot be reached at the present time save in a clinics with special facilities. While perfection is a goal which is never reached in human circles, there can be no justification for the underlying suggestion that something very close prevention of phlebotomosis cannot be reached. I base reasons for this statement on our observations in a Department of Health for Scotland Hospital at Ballochmyle, Ayrshire.

Towards the end of 1946 strenuous endeavours were commenced to institute a campaign in the surgical side of the hospital against post-operative phlebotomosis and pulmonary embolism. The treatment under treatment were general surgical, gynaecological, and nose, and throat. In the first six months of that campaign our efforts were directed at instructing the junior medical staff, the nursing staff, and the physiotherapists in the early diagnosis of phlebotomosis. Great endeavours were made to combat venous stasis by activity in bed, the abandoning of Fowler's position, encouraging early rising, and post-operative breathing exercises. During this period 671 operations were performed. Eight of these patients were diagnosed as developing thrombosis and were treated with heparin and/or dicoumarin, and in none of them did a fatal pulmonary embolism occur. There were five cases of sudden fatal pulmonary embolism in which phlebotomosis had not been diagnosed previously.

In the following twelve months an impressive difference was seen. 12 operations were performed, with nine cases of phlebotomosis and no fatal post-operative pulmonary embolisms. These cases were treated with heparin, and in no case was venous ligation or amputation carried out. If these figures are compared with those recorded by Bauer (*Lancet*, 1946, 1, 447) with reference to the pre-coagulant era, we find that post-operative thrombosis occurred in one patient in every 180, as against an expected rate of one in 1,622.

Further, fatal pulmonary embolism occurred in no patients out of 1,622, as against an expected rate of one in 360. Perhaps this can be regarded as "an iota of evidence" that pulmonary embolism is less frequent in at least one hospital without special facilities than it was "ten, fifteen, or twenty years ago."

There can be no doubt that femoral thrombectomy is not called for save in a relatively advanced case of phlebotomosis, and even in these cases satisfactory results accrue from ligation. The risks of producing pulmonary embolisms during thrombectomy are surely considerably greater than the risks of fatal pulmonary embolism under adequate heparin therapy. One could hardly expect any better success than our reports, namely three fatal pulmonary embolisms in 495 cases.

Mr. Bailey refers to the "unbridled use of expensive drugs." The average cost of treating a hospital patient with heparin for a recent and early phlebotomosis is about £14. When prolonged morbidity or actual loss of life is being averted such an amount of money can scarcely be regarded as excessive even from a purely economic point of view. I am convinced that any surgical unit which is determined to reduce its rate of post-operative phlebotomosis and pulmonary embolism can do so by adequate training within the unit and by the use of heparin when a case of phlebotomosis is diagnosed.—I am, Sir, Sir,

Mauchline, Ayrshire.

GAVIN J. CLELAND.

Clinical Value of E.S.R.

SIR.—Dr. J. Robertson Sinton's article (Feb. 28, p. 391) on the erythrocyte sedimentation rate was of great interest, but there are some points in his article to which I should like to draw attention. He mentions that the investigation was carried out at laboratory temperatures varying from 12° C. to 25° C. This is a wide range and surely tends to invalidate some of his figures. It has been shown by Westergren,¹ Ham and Curtis,² and others that a rise in temperature increases the rate of sedimentation; this, however, has been denied by Weingarten,³ who refutes the general statement that sedimentation rates are higher in warmer temperatures.

Table I shows readings taken simultaneously at 15.6° C. (60° F.) and 21.1° C. (70° F.) in a recent very small series of

cases. It will be noted that the temperature range is smaller than that of Dr. Sinton's, and the differences would be greater still with his wider range. The method used was the standard Westergren with 200 mm. tube, 1.6 ml. of blood, and 0.4 ml. of sodium citrate, and the readings were taken at the end of one hour.

TABLE I

Disease	15.6° C.	21.1° C.
Normal	8	12
Hodgkin's disease	6	10
Rheumatic fever	30	35
Pregnancy	11	15
Tonsillitis	15	22
"	12	16
"	20	30
"	17	25

An additional possible inaccuracy in the Westergren technique using sodium citrate is the measurement of the latter and the blood. To show the difference between a 1:4 and 1:3 ratio of blood to sodium citrate a few sedimentation rates were carried out at a constant temperature using these two dilutions, and the results are shown in tabular form below.

TABLE II

Disease	Ratio of Blood to Sodium Citrate	
	1:4	1:3
Normal	8	5
Rheumatic fever	6	4
Pregnancy	30	23
Tuberculous synovitis	35	24
Tonsillitis	13	7
"	15	10
"	32	22
"	12	8
"	16	11
"	14	9

An error of 0.1 to 0.2 ml. in measuring the blood or citrate may be sufficient to alter the ratio from 1:4 to 1:3—such an error may easily arise with the type of syringe usually used.

A final factor influencing the rate is the inclination of the tube. Westergren, Wintrobe and Landsberg,⁴ Ponder,⁵ and others all emphasize the necessity for the tube to be vertical: this is difficult to achieve. Moreover Ham and Curtis⁶ have shown that only 5° from the vertical produces a substantial error. A method of ensuring a vertical tube and also a constant temperature is that advocated by Rogers.⁷ In this the tube forms its own plumb-line, is plugged at its lower end, and is suspended in a large jar containing water at the desired temperature. The method is rapid, and the results may be directly compared—this is especially important in serial cases where the sedimentation rate is used as a guide to progress and in which normally a winter reading might be too low and a summer reading too high.—I am, etc.,

Medicine in a Planned Economy

SIR.—Finding myself very much in agreement with the trend of thought in the article by Dr. Ff. Roberts (March 13, p. 485) I cannot help adding the plea to all doctors in hospital or practice to be more thoughtful in their selection of, and demand for, specialized tests and laboratory examinations.

A friend who works in a large hospital in this city, where the patients are largely drawn from the upper age limits of the population, commented acidly to me on this very point the other day. As he puts it: "Subjecting an aged (75) arteriosclerotic with cerebral thrombosis to a full blood examination, lumbar puncture, and other examinations" may be an exaggeration of the actual state of affairs, but there is no doubt that a lot of tests (useless so far as the future of the patients is concerned) are being done. The minds of the younger members

of the profession are muddled by the ever increasing amount of scientific knowledge, and in their endeavour to keep up with and to apply that knowledge they are apt to get lost in a maze of often meaningless figures. The older clinicians in their endeavour to follow suit get lost even more easily. The language at the average residency table (to an outsider at least) would puzzle even an Egyptologist trying to unravel the mysterious message on some ancient papyrus. The nonsense being banded about on many lips in many spheres of life is becoming intolerable.

In school the new entrant is often measured by pseudo-scientific psychological tests. My own child was refused admission to school here because she did not reach up to the standard demanded by these tests. In fact, she was refused admission because she was "dull and backward." By other means I pressed her admission into this school—to find that the same "dull and backward" child shines now at or near the top of her class (no doubt a class of "backward" children). And so the nonsense goes round and round, using the words of the famous song. It is time some of us took a more sensible line, and Dr. Roberts is to be congratulated in reminding us this time of our failings.—I am, etc.,

The Treatment of Hyperidrosis

SIR,—Mr. H. A. Haxton (April 3, p. 636) in his opening paragraph states that essential hyperidrosis is seen in those parts of the body which are affected by mental or emotional sweating. He later goes on to say that the cause in most cases is unknown, and appears to discredit the theory of abnormal psychic disturbances, substantiating this by reference to a case in which the onset was before the age of ten years. As the genesis of most emotional disturbances occurs in infancy this would not appear to be a valid argument against the theory. It is to be noted also that in Case 5 the symptoms prevented the patient from dancing and in Case 9 occurred when the patient was warm or embarrassed—both of these would suggest an abnormal emotional background.

I have recently observed a patient, 34 years of age, in whom hyperidrosis of the hands commenced suddenly after a febrile illness, and in the early stages occurred only when the patient was playing cards, but later at frequent and apparently unconnected times. Varied local treatments were tried without success. About the same time the patient complained of praecordial pain and dyspeptic symptoms; these progressed to a frank anxiety state. Psycho-analysis revealed a deep emotional conflict of which the patient had been completely unaware. As the analysis proceeded the frequency of the hyperidrosis became less and less, and the patient was able to connect its occurrence with his conflict.

I would suggest that the majority of cases of hyperidrosis should be classified as psychosomatic, and in all cases where an organic cause is not found adequate psychological investigation should be carried out before submitting the patient to an operation, which although it may relieve his immediate symptoms will leave the basic cause unresolved.—I am, etc.,

JOHN H. L. CONWAY-HUGHES.

Pulmonary Embolism

SIR,—I am grateful to Mr. Norman C. Lake (March 20, p. 569) for giving some details of the necropsy findings in two of his cases, but I doubt whether he is right in blaming Nature for being preposterous as it seems probable that the necropsy examinations were not full enough to justify his conclusions. In his first case Mr. Lake states that clot was projecting into the superior vena cava from the azygos vein. This, I would submit, may refute rather than support his suggestion that the fatal embolus originated from this source. In the second case the fact that the clot was found projecting into the iliac veins (I take it that this refers to the internal iliac veins) is again no proof that this was the source of the embolus.

Let Mr. Lake should consider me unduly disputatious, may I add a few further remarks?

1. It must not be presumed that any veins containing ante-mortem thrombus at necropsy were the site of origin of a fatal embolus, unless (a) the veins of the legs have been carefully dissected, and (b) the loose clots in the heart and lungs can be shown to fit the veins from which they have allegedly

originated. Where these steps are taken there are very few cases in which an embolus can be proved to have arisen from those unusual sites which (in the absence of adequate necropsy examination) were formerly accepted as the source of some emboli.

2. In the ordinary necropsy, where examination rarely extends below the groins, it is frequently the empty rather than the clotted veins in which we should be most interested, and unless the leg veins are explored it is unjustifiable to incriminate the only veins that happen to have been examined.

3. Ante-mortem thrombosis is frequently extensive, and I have commonly found thrombosis at other sites when the veins of the lower limb were unquestionably the source of a fatal embolus. In the absence of full necropsy the wrong vein would have been incriminated.

I never doubted that Mr. Lake was fully aware of the importance of early movements nor did I think that he should have devoted much more space to the question of pulmonary embolus. I do, however, consider that his conclusions about these cases are unjustified and that it is singularly unfortunate that the little he did say should concern these two cases.

The purpose of my last letter was to challenge a too prevalent defeatist attitude to this subject of embolism. I fully appreciate that active movements alone will not prevent thrombosis, and it is for this reason that I would advocate daily examination of the legs and the "abortive" treatment of any thrombosis with heparin. If it be believed that thrombosis usually arises from the abdominal wall or from haemorrhoids, then there is little possibility of early diagnosis, and still less opportunity of selecting suitable subjects for anticoagulant therapy. This erroneous belief is disproved by the results of thorough necropsy examination.—I am, etc.,

Radlett, Herts.

REGINALD S. MURLEY.

Prostatectomy for Retention of Urine

SIR,—In the article by Mr. G. A. Bagot Walters on immediate prostatectomy for retention (April 3, p. 638) I read that recently as 1945 an excellent authority favourably compares the patient with acute retention operated on from the street at the bedded patient who has undergone "sulpha, catheter, anticipatory" treatment.

Now I think the comparison may be misleading. An acute retention with benign prostatic enlargement may frequently demand prostatectomy, whereas a patient catheterized for a few days or weeks may not need any debilitating "sulpha" treatment and certainly no confinement to bed with attendant loss of appetite and anxiety. In this rural area I remember twenty years ago how difficult it was to catheterize for more than a few days without having the depressing increasingly dirty condition of the urine brought to one's notice. From the time I commenced giving "metramine," one capsule daily, to mildly disinfect and make blue the urine I have not failed to keep it free from unpleasant odour or cloudiness, even after catheterization for some weeks in cottage conditions.

When one's experience is limited, it is unfortunate that hospital the only case of acute retention I saw decompress with a lumbar puncture needle suprapubically, died. In practice where catheterization has been imperative and possible I have always spent an hour in emptying the distended bladder—without very frequent interruptions in the flow—while engaging the patient in conversation and deprecating all efforts to assist expulsion.

Of my few elderly prostatic patients I give, as illustrations, what may happen, (1) a case refusing a second-stage operative satisfied to live and get about with a permanent and leaking suprapubic drainage emptying into a milk bottle suspended by tape from the neck of the patient; (2) two cases, both over 70 years, who after catheterization for some weeks resumed normal micturition for several years; (3) one case who had weeks of catheterization with "metramine" administration, without recovery of natural function, and who submitted to immediate and uneventful prostatectomy by a general surgeon; (4) one patient who died from heart attack a few days after suprapubic drainage had been established by an eminent genito-urinary surgeon; (5) one sturdy patient admitted to hospital without catheterization but with considerable residual urine, as shown by percussion, who died four days later from urinary suppression after suprapubic drainage; (6) one patient aged 80 years, who in 1947 had acute retention through unavoidable

play in micturition. This case gave a history of nocturnal frequency very many years. Owing to having an ailing wife he refused operation; catheterized daily for three weeks, and with metramine, he assumed natural micturition, getting up once nightly, and to-day is living a very active life.

I write these particulars for the rural practitioner who may be interested in the common things of life.—I am, etc.,

Haydon Bridge, Northumberland.

RICHARD BELL.

Malignant Syphilis

SIR.—The report headed "A Fatal Case of 'Malignant' syphilis" by Drs. Robert Lees and William Fowler (March 6, 1948) is of considerable interest. Although the occurrence of lupial lesions and mucous patches together with penile sores and a positive Wassermann reaction makes the diagnosis of syphilis extremely likely, it seems nevertheless a pity that apparently no attempt was made to demonstrate *Spirochaeta pallida* in genital or other lesions.

It would be interesting too to learn whether any Herxheimer reaction was noted on commencing treatment. No doubt the small initial dosage of penicillin was designed to prevent therapeutic shock. Yet recent American work would suggest that the risk of therapeutic shock is no greater with large initial doses of penicillin than it is with small ones.¹ Moreover, in the apparent absence of involvement of vital structures surely it would have been more logical to have begun treatment with large doses of penicillin plus a potent arsenical, plus a soluble bismuth or mercurial salt, in order to combat an apparently fulminating infection. A fulminating meningococcal septicæmia, for example, is regarded as requiring heavier dosage with sulphonamides than would a case of average severity.

Isolation of the spirochaete would also have made possible an attempt to determine by means of rabbit inoculation whether the infection was caused by a drug-fast strain such as that reported on by Beerman and Severac,² whilst microhistological investigation might have determined the condition of the smaller and medium vasculature, as vascular causes have been held responsible for destructive changes both in early and late syphilis.³

Lastly, occasional batches of penicillin are found to be therapeutically ineffective. Was the particular batch used tested and proved to be therapeutically active on another patient, or otherwise assayed for penicillin content?—I am, etc.,

Thiouracil in Thyrotoxic Heart Disease

SIR.—I feel that Dr. W. E. Clarke (March 27, p. 597) has been unlucky in his experience of treating thyrotoxic cardiovascular disease with thiouracil, since in many hospitals satisfactory results are being obtained. I have before me the notes of twelve consecutive cases of thyrotoxicosis that I have treated during the past year. Six had cardiac failure, and three of these auricular fibrillation. The degree of failure seemed more severe than in Dr. Clarke's cases, and the initial pulse rate was never below 120. In all six cases the cardiac symptoms were entirely relieved by thiouracil, the fibrillation reverting to normal rhythm, which has persisted. The condition of the patients, on a small maintenance dose, is excellent. Surgery was offered but was refused in every case, though in fairness it must be said that patients referred to a physician using thiouracil are in some sense selected. One woman, for example, had refused to go to hospital for years, until she was told that a non-operative treatment was available.

As regards the frequency of heart disease in thyrotoxicosis I would question the statement that few cases now develop cardiac complications. It would be safer to say that the thyrotoxic element in heart disease is often overlooked. No assessment of the incidence of thyrotoxic heart disease is valuable unless the age of the patients is taken into account. Of my twelve cases, those whose hearts failed were all over 44, while the others were all under 41 save one. I would suggest that in

the older patient cardiac failure may occur quite early in the illness.

Dr. Clarke does not give details of dosage, and it is possible that the drug fever and granulopenia which caused him to resort to surgery were associated with a higher dose than is used to-day. I have not used more than 200 mg. of the methyl derivative three times a day in the cases of which I have spoken. A mild granulopenia should not cause treatment to be given up. Of his other failures, neurosis seems an odd reason for surgical intervention, and malignant exophthalmos is seen after thyroidectomy. Of my own cases there are two in whom I should like to see the goitre removed for cosmetic reasons, but the patients will not hear of it.

Either thyroidectomy or thiouracil can control the symptoms of thyrotoxicosis with minimal risks if properly used. Operation will always be favoured by those who regard the goitre as the *font et origo mali*, but it is surely more correct to look upon it as a link in a disordered metabolic process. From the practical point of view patients to whom the alternatives are fairly presented will decide for themselves. It behoves us, by a careful follow-up, to see that we are in a position to present the facts.—I am, etc.,

Chesham, Surrey.

C. P. PETCH.

The Danger of Intubation under Trichlorethylene

SIR.—Dr. W. M. Maidlow (March 13, p. 523) rightly emphasizes the dangers of too early intubation. Intubation under trichlorethylene is often unsatisfactory, as the laryngeal and tracheal reflexes in the uncocainized patient are still active, and indeed under these conditions may be dangerous. This danger exists under all anaesthetics. Other fatalities have been reported, occurring immediately after intubation, when agents other than trichlorethylene have been employed. Early intubation can be necessary and is sometimes vital, but I feel there is a strong tendency to intubate in lighter and lighter planes of anaesthesia, more because of impatience or to satisfy a personal vanity than any other reason. Intubation should be reserved for those occasions which require it, and then only after adequate preparation of the patient.

Reflex spasm of all muscles of respiration occurs after early intubation, but I would hesitate to use curare in this condition, which always responds excellently to an increase in the anaesthetic concentration.—I am, etc.,

London, W 1

G. E. HALE ENDERBY.

"Myanesis" as a Relaxant in Children

SIR.—With reference to the article by Dr. W. H. Armstrong Davison (March 20, p. 544) I think the use of "myanesis" combined with general anaesthesia for Ramstedt's operation is a retrograde step. The operation can be carried out quite satisfactorily using local anaesthesia with procaine, and I feel that the use of a drug about which there is still a diversity of opinion is unjustifiable in these cases.

Dr. Armstrong Davison states that the objections to local anaesthesia are that the technique is time-consuming and relaxation is unsatisfactory. The time factor should not influence an anaesthetist where the safety of his patient is at stake. The degree of relaxation obtained with local anaesthesia is quite adequate for the operation, which can usually be performed using 10 ml. of 0.5% procaine, which is well within the safety limits of the drug.—I am, etc.,

London, W.C.1.

J. N. T. HUTTON.

Naming Drugs

SIR.—In reviews and abstracts of articles appearing in foreign periodicals it frequently happens that a familiar drug escapes recognition by being referred to under a name not in use in this country. A case in point was the reference to mandelamine (methenamine mandelate) in your leading article "Streptomycin Bactericidal" (Feb. 28, p. 399). Mandelamine is, of course, an American proprietary preparation, but it will not be readily apparent to everyone that methenamine is the name used in the United States Pharmacopoeia to describe the substance known in this country as hexamine ("urotropine"). Other examples, perhaps better known because more frequently encountered, but which still cause some confusion, are epinephrine (adrena-

line) and neostigmine ("prostigmin"). There are, of course, many others.

In the absence of an international nomenclature it would appear highly desirable that wherever possible English names should be given in parenthesis in such cases. The additional burden imposed upon reviewers and abstracters would be only a little greater than that demanded by your most excellent custom of inserting metric equivalents to follow quantities expressed in British units, and would, I am convinced, be more than outweighed by the resultant increase in the usefulness of the material.

Much of the trouble is caused by manufacturers of proprietary drugs who, having an organization on both sides of the Atlantic, choose two names for a particular substance and use one in the United States and the other over here. There may be good reasons for this course, but it would help very considerably if one name could be selected for use in both countries.—I am, etc.,

Manchester Royal Infirmary.

J. B. LLOYD,
Chief Pharmacist.

The Lazy Eye

SIR,—Having been engaged in school clinic work for over 35 years I have to admit I am much disappointed. At Tottenham alone I see some 2,000 children in a year, and in many cases have to deplore the child growing up with an amblyopic eye.

There are many reasons for this. We may get the child too late. At nine or ten the value of occlusion is rather problematical, and if strabismus starts at a very early age and we see the child when it starts school there may be no fixation in the squinting eye and occlusion is useless. Furthermore, without intelligent co-operation from the parents it is often impossible to overcome the amblyopia, and attendances are apt to be irregular. Again it is deplorable that children are not taught to recognize the letters much under seven, which makes the estimation of visual acuity difficult. And one must remember that a squinting eye may get quite straight and yet remain amblyopic.

If a gross error, say 5D of astigmatism, be corrected at the age of two, much better visual acuity will ultimately be attained than in a case in which glasses were only worn several years later, and this applies much more in cases of anisometropia. The difficulty is spotting the error at so early an age, and this can only be done objectively. A gross error can be recognized in a few seconds with the retinoscopy mirror, and I have endeavoured to get the school medical officer to do so whenever possible, and refer doubtful cases to me. Also if I find two or more children in a family with defective sight I ask to see all the younger ones, and in this way secure better vision and often forestall a squint.

One should remember that a visual acuity of 6/6 is compatible with 5D of hypermetropia, but such a case can be recognized undiluted. With 6/9 in each eye, a small error, and no symptoms, it is often inadvisable to order glasses as it may be difficult to get the child to wear them.—I am, etc.,

London W 1

T. W. LETCHWORTH

POINTS FROM LETTERS

Contracting Out of National Insurance

Mr. JOHN B. S. JAY (Ayr) writes: Dr. W. Reginald Wilson's much better leads me to mention that a petition entitled "National Insurance, the Right to Contract Out" may be had for 1d. from K.R.P. Publications, Ltd., 7, Victoria Street, Liverpool. It sets forth some little-known facts about national insurance, including facts about its origins and manner of introduction.

Two Masters

Dr. M. I. COTTE (Edinburgh) writes: I have had so little experience of general practice that it is with some hesitation that I take up my pen to criticize others who can write with so much more authority. I feel that the dilemma which so many feel they will suffer in the proposed Health Service due to their loyalty being divided between Government and patient is a dilemma in which a conscientious practitioner must even now often find himself. An insurance doctor, if he is to do his duty, must always bear in mind that he has a double loyalty. If the patient comes first and last then of course the Government or Health Society will become bankrupt. It is probable that many, perhaps most, general patients do not appreciate the double loyalty of insurance, nor have they any idea of the cost

of the medicines with which they are supplied. When I suggest a patient that a certain medicine is expensive and that someone had to pay for it, or that a certificate of incapacity for work is a ticket-of-leave-with-pocket-money, the reaction varies from indifference to righteous indignation. So I suggest that as far as the matter is concerned our grievance is not that we shall have two masters, but rather that one of them may be too demanding.

Easy Money

Dr. C. E. GOLDSBOROUGH (Rothwell Haigh, nr. Leeds) writes: One of the best arguments I have met against basic salary is that there is no legal obstacle to the wife of Dr. X (who is, say, in public health service), by virtue of her also being a doctor, to put up a brass plate now at her residence, and in four months' time qualifying for a life pension of £6 per week. This is no theoretical surmise.

Certificate Madness

Dr. W. B. JAMISON (Belfast) writes: The other day I signed an official-looking certificate designed, I think, by the Board of Health, to prove that my patient had not grown a normal leg to replace an artificial one since the date of his last certificate. This document entitles him to a few extra clothing coupons. Yesterday I signed another so that my patient might be entitled to use the lift in the building in which she is employed in a domestic capacity. I lift attendant had informed her that only those employees in possession of a doctor's certificate were allowed to use the lift.

Aetiology of the Common Cold

Dr. FRANK CORT (Whitburn, Durham) writes: I read with interest the remarks of Dr. C. H. Andrewes (March 20, p. 559) at the meeting of the Medical Society of London and the discussion on the aetiology of the common cold. In particular I notice Dr. Andrewes said that bringing together virus and patient was not enough to produce a cold, that it is possible that a great many people carried an aetiological agent of a cold in their noses until something happened to upset the balance between host and parasite and a cold followed.

In my view the onset of a common cold is entirely due to oedema of the local mucous membranes by the onset of sudden histamine activity in the patient, and within 24-36 hours the oedematous mucous membranes have become invaded by secondary invading organisms producing mucopurulent catarrh, which is so often the stage which we see in our patients.

If this theory is correct then it is logical that the administration of any antihistamine agent will abort a common cold if given at the early stage of oedema before secondary invasion has occurred. I have tried this with various antihistamine agents, and in all cases in which I have been fortunate enough to treat the case in the early oedematous stage the cold has been aborted in a few hours and no mucopurulent stage has supervened. . . .

I am now working on the theory that if a virus is responsible for it acts by rendering active histamine bodies produced by such changes of protein metabolism. . . . I should feel honoured to be Dr. Andrewes' opinions on my remarks and experiences.

Prevention of Prickly Heat

Dr. PERCY E. TURNER (Thames Ditton, Surrey) writes: Very soon after commencing work in Travancore in 1901 I became aware of the local custom of a regular "oil bath," and sometimes saw the process being carried out by a faithful wife. The husband's skin was first of all freely anointed with some coco-nut or other oil and rubbed on, and after he had sat in the sun for say twenty minutes letting it well soak in, the excess was then washed off with strong vegetable soap and hot water, and I came to associate the specially velvety appearance of the skin, as described by Lieut.-Col. C. F. Barber (Feb. 14, p. 317) with this custom. But at first I did not appreciate the due order of things, and tried the oil application on my own skin after bathing (as believed by Col. Barber for 50 years) the result being an immediate outbreak of acute prickliness. Then I came to appreciate that the oil on the wet, hot skin was the best technique, and so reversed the order of things, setting out as follows in my *Tropical Medical Manual* (p. 12, 3rd ed., 1942, The Salvation Army, I.H.Q.).

"The sodden condition of the skin produced by much sweating with perhaps an accentuated microbic activity, leads in many people to a very troublesome condition known as prickly heat. It will be noticed that the natives of the country, although also free sweating, practically never suffer from this trouble. The secret appears to be in their addition to the free use of oil to the skin, and it will be found that the following to a moderate extent of the same custom is of very great service in keeping those from Western lands also free in this respect. Either olive oil, fresh coco-nut oil, or some similar vegetable oil, or a mixture of one of these with an eighth part of lanoline, will make a suitable application, which should be rubbed well into the skin when dry and the excess pressed off with warm water and a mild soap, leaving the deep part of the skin soft and supple and free from irritation."

bility of Pills

R. ROBERT DORMER (Chingford, London, E.4) writes: The public compressed tablets "pills," and swallow them intact. I have as a result of this practice considerable personal experience of tablets passing through the digestive tract completely unaltered. It could appear from this that all solid drugs which are not very easily soluble should be dispensed with abundant pill excipient, or powders in readily soluble capsules. . . .

Iccated Stomach Substance

J.L. writes: Personal and family experience of treatment with variations of desiccated stomach over a period of seventeen years has made me feel that a few practical hints to those who prescribe and those who have to take this unpleasant product may not come amiss. The best way to take it appears to be in cold water, the colder the better. Stir the powder into the cold water quickly and it is off. Take another mouthful of cold water after it. It does mix easily and some is apt to remain on the glass, but do not spend time trying to make it mix. An ounce of water should carry about 10 g. of the powder. The water should be put in the glass, and the powder added.

A new tin is always more objectionable. The unpleasant taste and smell will diminish a little if the tin is left open for a night. . . .

Current Dislocation of the Shoulder

Dr. D. W. C. GAWNE (Hong Kong) writes: This sign has been seen in five cases of recurrent dislocation of the shoulder joint in three of recurrent subluxation. It is elicited with the patient sitting or standing or lying down.

The fingers of the hands are interlocked and the hands rested, arms down, upon the vertex of the head, or palms resting in the cleft of the neck. The arms are held in a natural and comfortable position (elbows 30 degrees forward). Standing in front of the patient, a hollowing out of the axilla with a relative prominence of the head of the humerus will be seen on the affected side. On extension the humeral head will be clearly felt, with little interposed between it and the skin. A hollow surrounds the head, into which the fingers can be sunk without difficulty, particularly laterally and anteriorly. On the normal side a thick muscular belly is interposed between the head of the humerus and the skin, which can be rolled on its side to side on the front of the head.

The sign is due to a wasting of the oblique portion of the scapularis, which arises from the dorsum and lateral margin of the scapula and runs upwards in front of the head of the humerus. In the arm is held in this position.

St Examination

Dr. T. J. O'CONNELL (Sligo) writes: Sometimes difficulty is experienced in getting a patient to co-operate when examining his chest with a stethoscope. This can frequently be overcome by the simple device of distending a paper bag and getting the patient to hold it in his mouth and nose. After a short time the breathing becomes deep and regular. This is an old cure for hiccup, and for a number of years I have found it useful when examining chests. Perhaps the method may be of use to others, especially when examining the chests of children and mental patients.

Text in Old Age

Dr. G. C. ADENEY (Ditchling, Sussex) writes: The review by F. Parkes Weber of Dr. Vischer's *Old Age* (March 13, 1951) will have been welcomed by many medical men and men who, like myself, are approaching their own senescence. The presentation of old age as a period which should, and will, make its own indispensable contribution to the human process—process, indeed, of which the real meaning has not yet been closed—is itself a contribution that will serve to stir us up and us thinking.

His concluding translation of a fine fragment of fifth-century Latin tempts me to offer in exchange the last stanza of Longfellow's *Veni Salutatibus*, q.v.

Christian Medical Group

Dr. NEVILLE BRADLEY, Hon. Secretary, Medical Prayer Union (14th End Cottage, Turville Heath, Henley-on-Thames), writes: Founded over 50 years ago the Medical Prayer Union has sought in various ways to foster fellowship among Christian doctors. It has organized the Missionary Breakfast at the Annual B.M.A. Meetings and another for medical students every year in the spring. It would not from many points of view that the time is opportune to link medical men and women in some more effective way in order to promote and maintain a distinctive Christian witness in what is tending to become an increasingly secularized and nationalized service. I hope to foster and support the medical missionary activities of the Church at home and overseas. Will any interested send me their suggestions regarding such a "Christian Medical Group"?

Obituary

JAMES MCINTOSH, M.D., LL.D.

Dr. James McIntosh who died at Aberdeen on April 5 at the age of 65, had been professor of pathology in the University of London and director of the Bland-Sutton Institute of Pathology at the Middlesex Hospital since 1920. His brilliant attainments and many activities had made his name familiar wherever medical research is in progress.

James McIntosh was educated at Robert Gordons College, Aberdeen, and at the University of Aberdeen, where he graduated M.B., Ch.B. in 1905 and gained the M.D. with the highest honours in 1908. The first part of his career was devoted almost exclusively to research in various subjects, until in 1920 at the age of 37, he was appointed professor of pathology in the University of London and director of the Bland-Sutton Institute of Pathology at the Middlesex Hospital. After taking up this position his main interest was still in research, but administrative, teaching, and routine pathological duties made their claims on his energies. He worked on many different pathological problems, but there can be traced four main threads which ran through the whole of his research career. These four threads were his work on syphilis, on anaerobic bacteria, on chemotherapy, and on virus diseases.

His study of syphilis dated from his earliest research work under Levaditi at the Pasteur Institute, Paris, where he held an Alexander Anderson Scholarship from 1905 to 1907. It was continued at Aberdeen, where he held a Carnegie Research Scholarship, and at the London Hospital from 1910 onwards. This period was one of great activity on this subject on the Continent and was marked by the introduction of salvarsan. At the London Hospital he worked under William Bulloch, to whom he expressed lifelong gratitude for the training he had given him in bacteriology. It was here that he first collaborated with Paul Fildes, and so began a long and fruitful partnership. Their work was concerned with the chemotherapy of syphilis and also with perfecting the technique of the Wassermann reaction. The technique devised by them at this time remained for many years the standard method of carrying out the Wassermann reaction.

McIntosh's researches on anaerobic bacteria commenced at the London Hospital, again in collaboration with Paul Fildes, and were continued by McIntosh working alone during the first world war. The results of this work were embodied in a Special Report to the Medical Research Committee in 1917, a publication which for long constituted the standard work on these infections. This work was continued, and further researches in this direction proved of considerable value in the second world war, when McIntosh was a member of the War Wounds Committee of the Medical Research Council.

His interest in chemotherapy also started early in his research career at the London Hospital, where he was working on the chemotherapy of syphilis with particular regard to the solubility and mode of action of the substances used. Fildes and he at this time noted the production of drug-resistant strains of micro-organisms. This work was continued later in connexion with the newly discovered sulphonamides in conjunction with Lionel Whitby and with the old partnership renewed when Fildes was installed in the Middlesex Hospital.

McIntosh first became interested in virus diseases when in his early years at the Pasteur Institute he investigated the infective agent of acute anterior poliomyelitis. This work was resumed at the London Hospital after the first world war in association with Hubert Turnbull. In 1921 Turnbull and McIntosh gave the first description of encephalo-myelitis occurring after vaccination, and after his appointment to the Bland-Sutton Institute of Pathology McIntosh continued his studies of virus diseases of the central nervous system. This subject formed the basis of his presidential address to the Section of Pathology of the Royal Society of Medicine in 1928. McIntosh consistently upheld the view that the lesions of post-vaccinal encephalo-myelitis were directly due to neural infection with the virus of vaccinia. This view was opposed by many of his colleagues, and for long he ploughed a lonely furrow in this respect. It was not until many years later that

his view was accepted as correct by the majority of his colleagues. In more recent years he was entrusted by the Ministry of Health with the task of investigating the occurrence of cases of encephalo-myelitis during the war.

He was a confirmed believer in the possibility of virus infection being the principal factor in the production of malignant disease and did a considerable amount of work on virus infections bearing this aspect in mind. This continued for many years, and may be said to have culminated in his key experiment in which he showed that tumours induced by chemical carcinogens could be propagated by means of cell-free filtrates. The importance of this experiment has not been completely realized even yet, although it is beginning to attract more attention both in this country and on the other side of the Atlantic. It may well prove to have established factors of fundamental importance in the aetiology of cancer. This work constituted his chief interest for the last few years of his life and has been the subject of numerous papers. At the time of his death he was still deeply interested in this side of his work, which he was exploring with the aid of the high-speed centrifuge and of the electron microscope.

In general the most outstanding features of his contributions to research were his ability to strike at the root of a problem and to design experiments which would throw light on the solution. What amounted almost to mechanical genius stood him in good stead, as did his ability to maintain a thread running throughout the whole of his work, and he made use of advances in other sciences which would have a bearing on his own immediate problems. His wide interests and reading in a large number of different subjects enabled him to make valuable use of knowledge which at first might appear unconnected with the problems of pathology.

Outside his activities in the Middlesex Hospital he gave his services freely for the benefit of pathological science. For many years he acted, as treasurer of the Pathological Society of Great Britain and Ireland and was its representative on the Library Committee of the Pathology Section of the Royal Society of Medicine. He also did a considerable amount of work for the Pathological and Bacteriological Laboratory Assistants' Association. He acted as examiner to the Universities of London, Cambridge, and Manchester, and for the Conjoint Board. He was a senior member of the Medical Research Club, in which he took a deep interest and to which he communicated a number of papers.

Naturally of a shy and retiring disposition, McIntosh would yet fight strongly for what he believed to be right, and he possessed a very wide circle of friends. His work was characterized by vision, enthusiasm, and perseverance, and his personal attributes of charm, sympathy, and understanding endeared him to his colleagues and gained him the loyalty of his assistants. He requires no other monument than the record of the additions to medical knowledge made by himself personally and by the Institute which he so wisely guided for twenty-eight years.

EDWARD DEANESLY, M.D., F.R.C.S.

Edward Deanesly, who died on March 31 at the age of 82, made an outstanding contribution to the advancement of medicine and in particular of surgical practice in the Midlands. He was born at Wincanton, Somerset, in 1866, the second son of a wine merchant of that town. He was educated at King's School, Bruton, and at University College, London. He graduated B.Sc. in 1886, and in the following year took his M.B. with first-class honours in forensic medicine. In 1888 he proceeded M.D., and in 1891 he took the F.R.C.S. Deanesly held the posts of house-surgeon, obstetrical officer, and house-physician at University College, which at that time boasted a brilliant staff. On the medical side Deanesly enjoyed the teaching of Boston, Sidney Ringer, William Gowers, and Thomas Barlow, and on the surgical side of Marcus Beck, Bilton Pollard, Richard Godlee, and Victor Horsley.

In 1893 Deanesly was appointed house-surgeon to the Wolverhampton and Staffordshire General Hospital, and from then until his retirement in 1931 his work was bound up with that of the hospital. He early recognized the importance, particularly in an industrial population, of the proper treatment of wounds, especially of the hands, and on relinquish-

ing his resident post in 1895 in order to enter general practice in Wolverhampton he accepted the newly created post of honorary casualty officer. His few years in general practice enabled Deanesly to gain a thorough knowledge of the stages of surgical disorders, and he himself always credited them to have added enormously to his judgment and efficiency as a surgeon. In 1891 he was appointed assistant surgeon, and finally full honorary surgeon to the hospital.

There was no branch of surgical work, except ophthalmic surgery, in which Deanesly was not at home. His published work included articles on hernia, prostatectomy, cerebra abscess, the surgery of the renal tract, and on abdominal surgery. In his later years he devoted much time to abdominal surgery, especially the treatment of gastric ulcer. Deanesly is regarded his work on the surgery of the kidneys and ureters as his most important contribution to medicine. He was first to describe the difference between ruptures of the ureter caused by direct violence and those caused by fractures of the pelvis. Possibly more important was the technique which he developed in the treatment of recent wounds. Deanesly allowed himself to be diverted into an increasingly elaborate aseptic technique. Himself a pupil of Christopher Heath, personally acquainted with Lawson Tait and Jordan Lloyd, he knew the brilliant results obtained by these surgeons. Early in his career he began to treat the lacerated wounds produced by factory or street accidents by dissecting out, after proper cleansing, the whole surface of the wound however deep, including all tissue too damaged to recover; he then closed the wound without stitches by a firm absorbent dressing and left it undisturbed for at least a week. This practice soon became his routine and was taught to all his house-surgeons in the early 'nineties.

The Royal Hospital, Wolverhampton, is a standing monument to Deanesly; when he joined, its staff was recruited from general practitioners working in the town. Deanesly saw that for a hospital to attain to the first rank its staff must include a proportion of consultants and specialists. He persuaded the board of management to adopt the then almost unheard-of step of offering financial inducement to men to promise to come on to the honorary staff. He recognized the importance of the application of pathology in medical practice, and it was he who persuaded the board to build the nucleus of the present pathological department, which was opened by Sir Clifford Albutt in 1914 and of which Prof. William Bayliss, now of the University of Toronto, was the first head.

Deanesly was one of the original members of the Surgical Union, now the Provincial Surgical Club, founded by the late Lord Moynihan. With this Society he visited Berlin, Paris, Rome, Vienna, and many other Continental centres of surgery. Before the work of the hospital took up the whole of his time Deanesly took an active part in the civic life of Wolverhampton. He was elected a member of the Town Council in 1901, and served on the education committee; he resigned in 1917, it is usually supposed to escape his duties as mayor. He was appointed a justice of the peace in 1918.

By nature a Conservative and a traditionalist, Deanesly never closed his mind to new ideas or ways of thought; his philosophy was to test all things and to cleave fast to that which is good, but before accepting it he required clear demonstration that a new way or idea actually was good. He hated cant, and his forthright personality made him impatient of minds less clear and less honest than his own. His mordant tongue and habit of sustained irony, combined with an impressive delivery, made him a stimulating if somewhat alarming speaker on public occasions. In private his quick wit, never better displayed than over the dessert and wine at his own table and those of his friends, always assured fruitful conversation. He read widely and deeply, particularly in philosophy and history, and to the end of his life maintained his interest in the classics.

On retirement from active practice Deanesly was appointed a vice-president of the Royal Hospital; he took up his residence at Cheltenham, but shortly after the outbreak of the second world war moved to Llanbedr, Merionethshire, where he died. His widow, daughter of the late Alderman John Marston, of Wolverhampton, survives him, together with two sons and three daughters.—S. C. D.

H. M. STRATFORD, F.R.C.S.Ed.

ard Stratford died very suddenly early on Good Friday home in Burwash, East Sussex. Although he was known to have suffered for some time from heart attacks his death was a shock to his many friends.

Edward Martin Stratford, who was born at Cirencester in 1872, was educated privately and later at schools in Norfolk and Gloucester. Brought up by his uncle, Dr. Drinkwater, of Cirencester, he acquired early in life his love for horses and dogs. His student days at Aberystwyth University and at Oxford entered King's College Hospital, where, after qualifying in 1900, he acted as house-surgeon to Mr. Boyce Barrow. He was interested in ear, nose, and throat work. Stratford later became registrar at the Royal Ear Hospital in Dean Street and at the Royal London Ear, Nose and Throat Hospital. He also held appointments at the London Lock Hospital, Hereford Infirmary, Colchester Hospital, and the Western General Dispensary, Marylebone. Later, after spending some time in Assam, tea plantation, he returned to England and started in practice in Wimbledon, remaining there for only a year or two. On taking the Edinburgh F.R.C.S. in 1913 he settled in Phillimore Place, Kensington, where he remained until his retirement in 1938. Up to 1914 he also had an office in the City, where he acted for insurance companies. Already a Territorial, he joined the R.A.M.C. on the outbreak of war, serving in France, Mesopotamia, Egypt, and Palestine, for the most part in field ambulances.

Dr. Stratford was medical officer to the Post Office in Kensington. He was a staunch B.M.A. man and had been honorary secretary and chairman of the Kensington Division. He was on the Council for a time and had also been president of the Metropolitan Counties Branch. As a representative of the Kensington Division for ten years he attended many annual meetings. An old member of the West London Medico-Chirurgical Society, Stratford had been honorary secretary and president. He was also a keen supporter of the Society of Members of the Royal College of Surgeons, of which he was president for a time. He attended regularly the annual meetings of fellows and members and frequently spoke there. He did at most Council meetings of the B.M.A. His last speech was three weeks ago at Hastings, where he voiced his strong feelings regarding the National Health Service Act. He had an intense interest in medical politics. He married Miss Sybil Gould, of Hampstead. To his widow and three who survive him our sympathy is extended.

Stratford was a warm-hearted and generous friend. He was a very ready speaker, and never pushed his opinions; but his many friends realized that when he did speak he talked with sense and was worth listening to. He had a sunny smile though he certainly did not wear his heart on his sleeve, a friendly nature.

Dr. H. H. Sanguinetti writes: With the sudden death of Edward Stratford there has passed from our midst a charming personality of the old school of doctors, not perhaps in high life in these bustling days but standing for an essential something which we may be in danger of losing at the present time. Edward Stratford was a die-hard—not by any means necessarily firm of reproach, for it is the die-hards who will preserve for our generations many of our most precious traditions. What Stratford believed in he gave himself to whole-heartedly, and the Kensington Division was fortunate in securing his services as secretary in 1923. Working devotedly for it, he succeeded in vivifying it. Rather than relinquish his work for the division naturally he suffered the writer to be elected chairman in 1927, but became chairman himself in 1929. His interest in the activities of the B.M.A. were shown further by his becoming secretary and in 1931 president of the Metropolitan Counties Branch, and his popularity with his fellow practitioners and consultants was again demonstrated by his election to the presidency of the West London Medico-Chirurgical Society. Stratford naturally joined up at once in 1914 and was with enthusiasm in the march to Jerusalem. His war service permanently damaged his health, and probably this was partly responsible for his retirement from practice before the last war. His retirement did not mean idleness or even loss of interest in things medical; the war provided many opportunities for

further work for which his previous experience had prepared him. I think he would have chosen a rapid ending to his life—restrictions would have been resented. He knew his life was precarious, but he was a gallant gentleman.

Dr. ARTHUR WINFIELD, who died on Jan. 26 at the early age of 60, was educated at Wigan Grammar School, Cambridge University, and the University of Liverpool. He obtained the Cambridge M.A. with honours in 1912, and qualified in 1917. He served abroad in the 1914-18 war as a surgical specialist with the acting rank of major. After the war he settled in practice in New Ferry, Cheshire, and continued there until his death. For many years he was honorary radiologist at the Birkenhead General Hospital. He was a member of the Liverpool Medical Institution and had been chairman of the Birkenhead and Wirral Division of the British Medical Association from 1941-3. He was also an active member of the St. John Ambulance Brigade and fulfilled the duties of police surgeon in his area. Marrying rather late in life, he lost his wife with tragic suddenness after only a few years. He will be remembered chiefly for his kindness and for his readiness to help all in need. Quiet and reserved in manner, he was a staunch friend, a wise physician, and an outstanding obstetrician. He had few interests outside his work, but reading and music were his chief forms of relaxation, and he was a flautist of no mean ability. His death robs the profession of a man who, though not easily roused, fought tenaciously to maintain medicine not only as a science but as an art and an ideal.—G.S.S.

Dr. DAVID LAING died in Arbroath, Angus, on Feb. 27 at the age of 86. He was born in Kirkcaldy, and studied at Edinburgh University, graduating M.B., Ch.B. in 1884, and proceeding M.D. in 1887. He entered general practice in Arbroath just over sixty years ago, and was a member of the visiting medical staff of Arbroath Infirmary from that time until his retirement in 1946, when he became honorary consulting physician to the Infirmary. During his long years of service he played an important part in its development, and was himself mainly responsible for the introduction and working of the x-ray department, to which he gave so much of his time and enthusiasm. Throughout his life in Arbroath he was closely connected with the Ambulance Associations and the Boy Scout movement, of which for many years he was district commissioner. He was an old volunteer and an officer of the Territorial Army, and was the holder of the Territorial Decoration. He had been a member of the British Medical Association since 1894, and was chairman of the County of Angus Division from 1940-4. During his long life in Arbroath as a general practitioner his cheerfulness and buoyancy of spirit became bywords in the burgh, and left behind a pleasant memory of a fine old gentleman.—W.C.C.

Dr. CLAUDE LIONEL COODE died on March 23 at the age of 73, in Stroud, where he had been in practice for over forty years. Dr. Coode was a student at Oxford and at the London Hospital. He graduated M.B., B.Ch. in 1903 and settled in general practice in Gloucestershire after a period as surgical assistant at the out-patients' department of the London Hospital. He was later house-surgeon to Stroud General Hospital and subsequently, in 1907, honorary assistant surgeon and finally consulting surgeon there. Dr. Coode was largely responsible for starting the x-ray department and later the ear, nose, and throat department at the hospital. Apart from his professional activities Dr. Coode found recreation in sailing and in the study of natural history. He had been an active member of the British Medical Association for many years and was president of the Gloucestershire Branch in 1927-8.

Dr. WILLIAM HENRY JOHNSTON died on March 23 at his home in Tufnell Park, London, at the age of 62. A native of County Tyrone, Dr. Johnston was educated at the Royal School, Dungannon, and the Royal College of Surgeons in Ireland, qualifying in 1912. He worked for a time at the North-West Hospital, Hampstead, before serving in the 1914-18 war with the rank of captain, R.A.M.C. After the war he was in general practice at Fortress Road, N.W.5, and subsequently at Junction Road, N.19, where he remained until his death. At the outbreak of the recent war he was temporarily in charge of a civilian casualty evacuation train.

Dr. GEORGE ROBERT PHILIPSON, of Whitley Bay, Northumberland, died on March 26 at the age of 71 after a short illness. He graduated M.B., B.S. in 1906 from Durham University Medical College, and was a house-surgeon and house-physician at the Royal Victoria Infirmary, Newcastle-upon-Tyne. He was

in general practice for a number of years at Belford and Wallsend before coming, in 1924, to Whitley Bay, where he was in practice up to the time of his death. A native of Allendale, Northumberland, he had a life-long association with the Methodist Church, and was an active member and trustee of the Oxford Street Church at Whitley Bay. A man of quiet character, he was much loved by his patients. He leaves a widow, a son, and two daughters.

Dr. DONALD KERR MACDOUGALL, who died on April 4, was one of the most valued and trusted members of the profession in Southport. He graduated M.B., Ch.B. at Glasgow in 1915, and then served with the R.A.M.C. in Mesopotamia and in India during the first world war. Settling in practice in Southport in 1920, he developed ear, nose, and throat work as a specialty. For many years he was assistant surgeon to the ear, nose, and throat department of Southport Infirmary, and on retirement he was appointed consulting surgeon. The whole burden of work in this department was shouldered by him during the second world war, and he acted in a similar capacity at the Southport Emergency Service Hospital. Many other honorary and public appointments were held by him. He was chairman of the Southport Division of the British Medical Association in 1937-8, and a past president and secretary of the Southport Medical Society. He maintained a keen interest throughout the years he practised in Southport in the work of the Association and of the Society, and his sound and experienced advice was often sought in their management. A Gaelic scholar of note, he was possessed of a whimsical quality of mind which endeared him to his closest friends and lent him a charm appreciated by colleagues and patients alike. Conscious of the serious nature of his illness in the last few months of his life, he retained his whimsicality, and this and his courage made a visit to "Mac" the same delight in illness as it had been when he was in robust health. We mourn his loss and extend our deepest sympathy to his widow and three children.—P. Y. L.

Dr. ARTHUR WILLIAM LATHAM died at his home in Llanaber, North Wales, on April 4 after a long and painful illness borne with great fortitude. He was born at Haydock, near St. Helens, and was educated at Owens College, Manchester, where he had a distinguished career. He graduated M.B., Ch.B. in 1902, and proceeded M.D. two years later. He gained a fellowship in medicine in 1902-3, obtaining a gold medal. Dr. Latham had an extensive practice in St. Helens for over forty years, retiring only in 1946. He was an honorary surgeon at the St. Helens Hospital, medical officer to the Post Office, and a colliery doctor. In 1934 he was made a J.P. and sat on the St. Helens Bench. Dr. Latham took a great interest in sport, and was honorary surgeon to the St. Helens Rugby Football Club. He was an active member of the St. Helens Division of the B.M.A., and was chairman in 1927-8. Our sympathy goes out to his widow and his two daughters, both of whom are married. A.A.W.M.

Medico-Legal

ALLEGED CONSPIRACY TO PROCURE MISCARRIAGES

At Marylebone police-court on April 7, before Mr. Rowland Thomas, K.C., two women doctors, Dr. Eleonore Bergmann, of Park Square, N.W., and Dr. Mary Bell Ferguson, of Devonshire Place, together with Mrs. Pauline Mary Evans, Dr. Bergmann's receptionist, were charged with conspiring together and with others unknown unlawfully to procure miscarriages. Mr. H. A. K. Morgan prosecuted. Mr. Gerald Howard defended Dr. Ferguson, and Mr. B. B. Gillis and Mr. A. J. Wrottesley defended Dr. Bergmann and Mrs. Evans. Dr. Bergmann was also charged with having attempted to commit suicide. Counsel for the defence said that at the right time defendants would make clear their answer to the charges.

Mr. Morgan referred at the outset to the statement of the law in such cases which was given by Mr. Justice Macnaghten in *Rex v. Bourne* at the Central Criminal Court in 1938. The judge then said:

"If the Crown fail to satisfy the jury that it [the procuring of the miscarriage] was not done for the purpose of preserving the life of the mother, then my direction to you here is that your verdict

should be a verdict of 'Not Guilty.' If, on the other hand, the Crown do satisfy you that they have discharged the burden upon them under the section [Infant Life Preservation Act, section 1] then your verdict should be 'Guilty.'" His lordship continued, "The law does not permit the termination of pregnancy except for the purpose of preserving the life of the mother. I say myself that those words ought to be construed in a reasonable sense; if the doctor is of opinion, on reasonable grounds, and adequate knowledge, that the probable consequence of the continuance of pregnancy would indeed make the woman a physical or mental wreck, then he operates in that belief for the purpose only of preserving the life of the mother."

The case for the Crown, Mr. Morgan went on, was that none of the four instances brought forward did Dr. Bergmann operate, even in this wide sense, for the preservation of the life of the mother, and that in the two cases in which Dr. Ferguson gave a certificate it was not an honest expression of her belief that operation was necessary to that end, but was given as a cloak to cover Dr. Bergmann's activities.

The first case—in which Dr. Ferguson was not concerned—was that of a married woman employed as a staff nurse at a hospital. Realizing she was pregnant, and that it would be practically impossible for her to get accommodation if she had a child, she went to Dr. Bergmann, who confirmed the pregnancy but at first refused to do anything to terminate it. Eventually, however, she yielded to the woman's pleading. When seen by the police-inspector at a later date Dr. Bergmann said, "Fancy Mrs. ——— doing this to me. I knew it was wrong. I first refused to help her. How on earth did you find out about it?" The inspector then mentioned other cases. Dr. Bergmann made a statement about each. She had performed an operation under pentothal to terminate pregnancy. The first woman stated that she gave £10 to the receptionist who herself received £5 in this and in each of the other cases. The receptionist had stated that Dr. Bergmann had told her that she never terminated a pregnancy unless she had a certificate from another doctor stating that this was necessary in the interests of the health of the mother.

The second case was that of a single woman, a student, in November last suspected pregnancy, which was confirmed by her family doctor, who also said that she was quite healthy and perfectly capable of bearing a child. The woman made an appointment to see Dr. Bergmann, and broke down and crying pointed out her unmarried condition and family difficulties. Dr. Bergmann suggested that she should see Dr. Ferguson, who was a specialist in psychoneurotic cases. Dr. Ferguson examined her and ultimately gave her a letter for Dr. Bergmann stating that she was of a neurotic type, that her reaction to children was pathological, that she was unbalanced in her attitude to life, and mortally afraid of her father. The fee paid to Dr. Ferguson was three guineas. Dr. Bergmann gave her a pentothal injection and carried out the operation. The fee paid was £75. Dr. Ferguson, questioned by the inspector concerning this case, was alleged to have stated that she had no doubt that the girl would have had a nervous breakdown if the pregnancy continued.

In the third case the woman was again recommended by Dr. Bergmann to see Dr. Ferguson, who at first advised her to have the child and get it adopted, but the girl said that this was out of the question, and ultimately Dr. Ferguson wrote a letter stating that the girl was in an anxiety state, that in fact there was a vicious circle—she was exhausted, was anxious, did not sleep, and so became more exhausted—and that it would be better for her health, bodily and mental, if the pregnancy was terminated. She also stated that the girl had had a very bad attack of jaundice a few months previously. In this case £75 was paid to Dr. Bergmann.

The fourth case was that of a woman who had had a baby in June of last year, and at Christmas found herself again pregnant. She was married but had kept her marriage secret. In this case a fee of £50 was paid.

The four women concerned, whose names were not divulged, gave evidence to the above effect. In the two cases in which Dr. Ferguson's name was mentioned Mr. Gerald Howard asked the witnesses whether it would not be fair to say that Dr. Ferguson elicited a complete picture of their history and their physical and mental condition, and they agreed that it was so. One of them added that Dr. Ferguson talked to her

eight minutes to go . . .

Doctors today find that a large number of their patients complain of constant tiredness, of 'finding everything too much', of 'feeling generally run down'. Cases of debility and lassitude caused by present-day conditions are becoming increasingly prevalent. For these conditions 'Vibelan' is of particular value. It counteracts B vitamin deficiencies, containing as it does the principal members of the B group in the balanced proportions which are necessary for effective utilisation of proteins, fats and,

more especially, carbohydrates. Each tablet contains vitamin B₁ 0.5 mg., riboflavine 0.75 mg. and nicotinamide 7.5 mg., in a yeast extract base. Four tablets provide the normal daily requirement of these vitamins. 'Vibelan' is available in bottles of 50 tablets. Further details are available on request.

HANDS AND THE MAN . . . No. 1

Mr.,

Specialist in Abdominal Surgery

When clever hands move with calm speed to the crux of the operation—then the ligatures which complete the job must be equally perfect. The Ethicon organisation holds the enviable, but highly responsible, post of leadership in sutures. Their achievement is not so much that they make more sutures than anyone in the world—but that they make sutures which are outstanding in quality and reliability.

View the Ethicon Sutures through your usual Surgical Supply House.
 All Ethicon Sutures sold in Great Britain are entirely British made.

ORAL PENICILLIN THERAPY

Clinical studies show that 'Tabloid' brand Penicillin (buffered with sodium citrate), in doses of three to five times those given by parenteral routes, maintains equivalent or higher serum levels and produces a comparable therapeutic response. The increased dosage necessary by the oral route is more than offset by its greater convenience and by the saving in professional time and attention.

'Tabloid' brand Penicillin is issued in bottles of 20 at 14/- (subject to professional discount). Each product contains calcium penicillin 20,000 I.U. and sodium citrate, 0.5 gm. Literature is available on request. A desiccant is now included in each pack to protect the products from moisture.

a long time, examined her lungs, took her blood pressure, asked about her family. She was with her for about three-quarters of an hour.

r. Alexander D. Petro, of Wilton Place, testified with regard to the third woman that she came to see him and at her request he tested her for pregnancy and also examined her ecologically. He told her that he saw no reason why she should not have a baby. Similar evidence was given with regard to the other of the women by her family practitioner. The hearing was resumed on April 13, when all three defendants were sent for trial.

Medical Notes in Parliament

NATIONAL HEALTH SERVICE

MR. BEVAN'S STATEMENT

Minister of Health made the following statement in the House of Commons on Wednesday, April 7: "I think that the time has come for me to make a statement to the House about the medical profession and the National Health Service. Needless to say, I make this statement on behalf both of the Secretary of State for Scotland and myself, of the Government as a whole.

I have been receiving representations from many quarters, the Royal College of Physicians and the British Medical Association have sent me—and which have since been published and are familiar to the House. Meanwhile I have been trying, so far as I am able, also to determine for myself what it is that is really and sincerely worrying the doctor.

No doubt, as we gain experience, we shall find many modifications which would improve the scheme. That is always true of major legislation of this kind. But it seems to me that it is somewhere beyond all this that the key to the doctors' uneasiness and restlessness lies, and that it consists of some instinctive feeling—shared by many most well-meaning men and women—that although the Act does not propose it and although the Government have themselves denied it, the real objective is a full-time, salaried State medical service. It is this fundamental issue which I want now to tackle once and for all. As long as we are in this House, I said:

"Some doctors have expressed the fear that this is merely the beginning of a full-time salaried service. I cannot read the mind of any future Minister or prophesy what may be done by future Governments, but that is not our intention." (*Guardian*, Nov. 4, 1946; vol. 428, c. 1125.)

It seems clear that something more than my spoken assurance is needed, and I am certainly quite willing to do what is needed to banish this apprehension for good. The Royal College of Physicians has made the useful suggestion, with which the other Royal Colleges associate themselves, that I should now make it statutorily clear that a whole-time service will not be brought in by regulation, but would require further legislation to make it possible. My colleagues and I accept this most cordially. In short, we propose that it should be impossible to institute a full-time salaried service by regulation alone. It would then need express legislation if it is ever proposed.

As the House knows, I am about to set up an expert legal committee to advise me on the disputed effect of the Act on partnership agreements. I hope to announce details of this committee at Question Time to-morrow. It seems likely that a clarifying Bill may be needed as a result of its inquiries. So, I shall take the opportunity—and, if not, I shall invoke the opportunity specially—to ask Parliament also to clarify its intentions about any full-time salaried service in the way suggested above.

There is one further way, in which we can eliminate these apparently widespread fears of a full-time salaried service. By many doctors the proposed fixed element of £300 remuneration seems itself to be a menacing thing to fear. I for my part have always conceived it rather as an allowance for the young beginner and for the older practitioner wishing to ease up in old age, and as a peg on which to hang additional assured payments for doubtful areas or other services—and these are all worthy objects. However, if doctors are afraid of sinister intentions in this, I think these worthy objects can be achieved in another way, and no amendment of the Act is needed for this. Let all new entrants to practice receive the advantage of this assured element of £300 for a period of say, three years. Then let each decide for himself whether he will forgo it and pass to a system of plain capitation fees,

or stay as he is with his fixed £300 plus a lower proportionate rate of capitation. He will be able to do this at any time. Similarly, let any doctor in established practice be able to elect for himself at any time to go on to the system of £300 fixed payment, plus the lower capitation rate, if and when he wants to—for example, in old age—instead of the higher rate with no fixed payment at all.

So now it can rest with the individual doctor himself to decide the extent to which he prefers the combined system of £300 plus lower capitation, or all capitation—with the exception that beginners will start with three years on the former system.

One other point. I have already given assurances in this House that I do not for one moment intend to interfere with the ordinary rights of doctors to express themselves in speech or in writing with absolute freedom. Similarly I have already given assurances to the profession that the Chairman of the Tribunal under the Act will be a lawyer of high professional standing appointed by the Lord Chancellor. I need scarcely repeat such assurances now, but—for the removal of any vestige of doubt—I do so.

I trust that what I have said will finally free doctors from any fears that they are to be turned in some way into "salaried civil servants." I look forward now to a future of active and friendly co-operation with the profession in putting into operation next July a great social measure which can be made a turning point in the social history of this country and an example to the world.

MR. OLIVER STANLEY: All of us in this House hope that when this National Health Service scheme comes into force it shall come in a form which will command the whole-hearted co-operation of the doctors. It always has been, and it still is, for them to decide, and I shall make no comment on the proposals which the right hon. Gentleman has made; but I am sure that speaking for everyone on this side of the House we welcome anything which tends to break the deadlock which has occurred, and above all we welcome the tone in which the right hon. Gentleman has spoken to-day.

MR. CLEMENT DAVIES: May I, on behalf of my colleagues and, I am sure, on behalf of everyone in this House, congratulate the right hon. Gentleman upon the action which he has taken and the statement he has made. I am quite sure it is the desire of every one of us that the National Health Service should work smoothly and harmoniously. I should like to ask him whether he is prepared—as I am sure he is—to meet the Negotiating Committee at once if they desire to see him.

MR. BEVAN: As I have said on many previous occasions, and as my right hon. Friend the Prime Minister declared quite recently, I am always prepared to meet the Negotiating Committee when they desire to see me.

DR. HADEN GUEST: May I also congratulate the Minister on this decision very largely on the ground that it will secure that the Service will begin with the good feeling of the doctors and the good feeling of the whole country in this matter—a most important aspect of this new service?

MR. WILSON HARRIS: Will the right hon. Gentleman clarify his very encouraging statement in two respects? First, will he give an assurance that no influence will be brought to bear on the doctors in the matter of issuing sickness certificates? Secondly, with regard to the basic salary, the formal suggestion of the Royal College of Physicians seems to leave it open—I am sure it is not the right hon. Gentleman's desire—to any Minister to raise the £300 by regulation to £600, £900, or any figure so long as it does not constitute a whole-time salaried medical service? Would the right hon. Gentleman be willing to go as far as to put into the amending Bill a provision that the original sum of £300 should not be increased except by a new Act of Parliament?

MR. BEVAN: That is a point of refinement which can be looked into later on. I am perfectly prepared to discuss the terms of the amendment with the representatives of the medical profession. I should like to take this opportunity of pointing out that there is very considerable misapprehension on this matter. People appear to think that the power to make terms and conditions of employment by regulation is something the Minister himself wants. The fact is that it is usually what the professions themselves desire, because it makes the whole system much more flexible. If we had to have an amending Act every time we altered the terms and conditions of remuneration, very often they would not be altered. The recent increase in capitation would not have been possible except by regulation.

SIR ERNEST GRAHAM-LITTLE: The right hon. Gentleman has asked what the doctors and the profession want. He has only mentioned one very important objection, and that is the fear of a full-time salaried service. I was present at the meeting of the Royal College of Physicians at which this resolution

was passed, and I should like to ask this question—will the Minister take into consideration the second motion which has been published in the Press, and which was moved at the meeting of the Royal College of Physicians, and accepted by them?

MR. BEVAN: I am always prepared to receive any representations made to me either by the Negotiating Committee or by the Royal Colleges.

MR. BAIRD: As the Minister to-day has been very generous to the British Medical Association, will he take into consideration the disquiet felt by Members on this side of the House about the delay in setting up health centres, and will he also consider making a gesture to this side of the House by speeding up the building of health centres?

MR. BEVAN: That lies rather outside the scope of the statement I have made, which is concerned with the terms and conditions of remuneration of the general practitioners. I hope, however, that the statement I have made will elicit from the representatives of the doctors the same spirit of cordial co-operation.

MISS BACON: Arising out of the last statement made by the Member for London University (Sir E. Graham-Little), is my right hon. Friend aware that any further concessions made by him will not be welcomed by many of us on this side of the House?

MR. BEVAN: It will be the opinion of hon. Members in all parts of the House and of the general public that the Government have gone a very considerable way to meet the profession, and it now lies with the profession to show an equal desire to make the National Health Service a success.

MR. RANKIN: Will my right hon. Friend clear up one point? If at the end of three years a doctor decides to continue receiving the £300 basic salary will he have to accept the lower capitation fee?

MR. BEVAN: Most certainly. He cannot have the £300 basic salary plus the higher capitation rate. He must take one or the other. The advantage of the proposal that I made is that the extent to which a fixed element is in existence will depend upon the initiative of the doctors themselves, and upon no one else.

DR. SUGAT: In view of the cordial reception given from all parts of the House to the Minister's statement, will he now himself take the initiative in inviting the Negotiating Committee to meet with him to discuss their remaining fears about the National Health Service?

HON. MEMBERS: No.

MR. BEVAN: Right hon. and hon. Members in all parts of the House will realize that the prestige of Parliament must be sustained. I am always ready to meet representatives of the medical profession. I should like to point out that we have sent to them in the course of the last few months a considerable number of letters asking for their co-operation on technical matters, and we have not received that co-operation.

MR. GALLAGHER: While agreeing that it is very desirable that the National Health Service should start off in a healthy manner, would it be permissible for the Government or the Minister to advise the workers to show the same solidarity and tenacity as the doctors?

House of Lords

A similar statement was made in the House of Lords on the same day by Lord ADDISON. Commenting on it, Lord SALISBURY said it deserved and needed a good deal more consideration. In addition the House of Lords would wish to scrutinize the legislation which he understood to be envisaged. It was evident that the Government were making efforts to break the deadlock between them and the medical profession. Everyone hoped that the proposal now put forward would result in an agreement satisfactory not only to the Government but to the medical profession, to whom all owed so great a debt for their selfless endeavours.

Lord SALISBURY said the statement made by Lord Addison could be taken to indicate the probability of a settlement between the two contending parties. As such it would be welcomed with great pleasure in all quarters. It must be a special satisfaction to Lord Addison to announce a measure of reassurance to the profession of which he had been so distinguished a member. The House would also wish to congratulate Lord Moran who, as President of the Royal College of Physicians, had done much to promote a settlement of the controversy.

Lord MORAN thanked Lord Addison and congratulated Mr. Bevan on what he had said in another place. Lord Moran also enthusiastically welcomed the statement. The Health Act had been forced for what it might become. Doctors had dreaded that it might be the prelude to a whole-time medical service. The Government's amendment of the Act Mr. Bevan had introduced had been possible to remove that dread. He had told the representatives which some had made to him by

making the basic salary optional after three years in practice. The Minister had boldly met the main fears of the doctors. Lord Moran hoped he would be rewarded by the loyal support of all reasonable members of the profession. He felt the doctors would now set their minds to the task of making this service under very difficult circumstances a turning point as Mr. Bevan had said, in the social history of the country.

Legal Committee Appointed

On April 8 Mr. MONSLOW asked the Minister of Health whether he had any statement to make with regard to a legal committee which he proposed to appoint to advise whether the National Health Service Act ought to be amended to secure an equitable result between partners in medical practice.

MR. BEVAN replied that he was glad to say he had been fortunate enough to enlist the services of the following gentlemen: Mr. G. O. Slade, K.C. (Chairman), Mr. Colin Phipps, C.B.E., Sir Cyril Radcliffe, K.C., Mr. J. H. Stamp, and for the Scottish Bar, Mr. J. R. Philip, K.C. The terms of reference were as follows:

To consider whether, in the application of the principles set out below to partnerships existing at the appointed day, it is desirable, in order to secure an equitable result as between partners, to amend Sections 35 and 36 of the National Health Service Act 1946, either by clarification of the provisions thereof or by extension of the powers thereby conferred or in some other way and to make recommendations accordingly.

The principles above referred to are:

(1) The general prohibition of the sale or purchase of the goodwill or any part of the goodwill of the medical practice of a medical practitioner whose name is on the appointed day or at any time thereafter entered on a list prepared under Section 33 (2) of the Act is to be maintained.

(2) Compensation is to be paid on the lines set out in Section 36 to practitioners whose names are on the appointed day entered on any such list, and subject to the provisions of Section 37, to such practitioners only.

(3) Practice in partnership is to be encouraged, and, except for the purpose of securing an equitable result, there should be as little interference as possible with the continued operation of existing partnerships.

(4) Within the general principle of the prohibition of sale and purchase of goodwill, exceptions in relation to sales or purchases in pursuance of a partnership agreement existing at the appointed day are permissible, if they appear necessary to secure the equitable working of these principles in relation to doctors practising in partnership.

(5) The possibility of legislation to make some addition to the sum of £66 millions, for which provision is made in Section 34 in order to meet cases which might arise if doctors whose names were entered on a list at the appointed day were required, in pursuance of a partnership agreement existing at that date, to buy the goodwill of doctors whose names were not so entered, is to be excluded if such an addition appears to be necessary in order to secure an equitable distribution of the £66 millions between doctors whose names are entered on a list at the appointed day.

Purchase Tax on Drugs

During his Budget speech on April 6 Sir STAFFORD CRIER said he was working out, with Mr. Aneurin Bevan, proposals for widening the scope of the present exemption for essential medicines. Hitherto the exemption list had been restricted to certain more costly preparations, but he and Mr. Bevan proposed to extend it to include a much wider range of non-proprietary medicines. A provision with this object would be included in the Finance Bill.

Diabetics Denied Pensions

MR. GRANVILLE SHARP raised, on April 7, the claim to disability pensions of men who, after serving in the Forces during the last war, had been discharged on medical grounds as suffering from diabetes mellitus. The Minister of Pensions had stated on March 6 that whereas 3,600 men were discharged from the Forces suffering from this disease, only 600 of the number had applied for a pension had succeeded in their claim.

DR. H. B. MORGAN said the Minister was in a difficult position. He had to take the advice of his experts. The bulk of the men who got into Government Departments seemed to lack the great deal of that human feeling which they should have received as applicants.

MR. THORNTON-KEMSLEY: "That is why doctors do not want to be State servants."

DR. MORGAN said that when a man got into the Ministry of Pensions he knew very little of what he was taking on.

The new laws come into operation on Jan. 1, 1949. Candidates who have appeared for the Fellowship examination on or before March 15, 1948, will be allowed to reappear for the examination at any time under the conditions set forth in the laws at present in operation. Candidates who appear for the examination for the first time on June 28, 1948, and are unsuccessful will have an opportunity of reappearing for the examination on Oct. 1, 1948, under the existing laws, but thereafter, if necessary, they must reappear under the new laws. Candidates who appear for the examination for the first time on Oct. 1, 1948, and are unsuccessful must thereafter appear under the new laws.

EPIDEMIOLOGICAL NOTES

Measles

The rise in notifications in recent weeks has been disproportionate and somewhat out of rhythm. Although no explanation of this trend can be offered, consideration of the pattern of notifications in the country makes the rise more easily understood.

Since general notification began in 1940 there have been four biennial periods in each of which the main epidemic peak came in the early months of the second year, following a gradual rise during the whole of the first year. During each of the first three two-year periods the last three months of the second year were periods of sub-epidemic level. At present (the early part of the first year of the fifth biennial period) notifications are at an exceptionally high level, and the rate of increase is more rapid than at the corresponding period in previous "even" years.

The main difference from previous periods seems to be the absence of the expected quiescent period in the last months of 1947. A rise in incidence followed immediately upon the subsidence of the main 1947 epidemic, and a comparatively high level had already been attained by the beginning of 1948. Present levels of incidence are greatly in excess of those at the corresponding time in 1946 in all parts of the country, the proportionate increase being greater in some districts than in others.

In the following counties the figures have already exceeded the maximum weekly figure during 1946-7, and are still rising: Herts, London, Norfolk, Peterborough.

In Middlesex and Surrey the notifications, having reached weekly figures nearly as large as the 1946-7 maximum, are still rising.

The following, having reached figures in excess of the maximum weekly figures in 1946-7, seem to have passed their peak and the figures are now declining: Cornwall, Northants, and the Holland, Kesteven, and Lindsey divisions of Lincolnshire.

It is noteworthy that London and Norfolk are both among the above-mentioned counties. In the previous biennial period these two counties, with East Suffolk, formed a small group which differed from the rest of the country in having the maximum incidence in the first, instead of the second, year. Two possibilities present themselves:

1. That the present incidence is the beginning of a two-year cycle similar to the previous four and leading to an unprecedented maximum at the beginning of 1949. Against this are the facts that (a) the rate of increase is more rapid than at the same stage in previous epidemics; (b) the rise began well before the beginning of the year; and (c) as mentioned above, some counties have already passed their peak and begun to decline.

2. That the present trend is unique in experience since notification began, and that we are now approaching a maximum for the whole country in the "even" year.

Forecasting what may now happen is largely guesswork. In 1946-7 certain towns (e.g., London, Sunderland, and Liverpool) began to show an increasing incidence early in 1946 and came to a maximum in the summer of that year, each having a further epidemic in the summer of 1947. England and Wales may possibly follow the lead of these towns, in which case we can expect two maxima in 1948-9, one in the summer of each year. On the other hand, if a sufficiently large part of the country remains on the rhythm of the winter-spring epidemic we may expect the figures for the whole country to show two peaks, one in the summer of 1948 and the other early in 1949. It seems inevitable that there will be a high incidence this summer, and this may be welcomed as being likely to reduce the case fatality even further.

Poliomyelitis

The number of notifications (uncorrected) in England and Wales in the week ended March 27 was: poliomyelitis 17 (20); polio-encephalitis 1 (2). Figures for the previous week are given in parentheses.

It is of some interest to compare the experience of the beginning of this year with that of the beginning of 1939. The year 1938 was the year of highest incidence before 1947. The total number of notifications in the thirteen weeks ended April 1, 1939, was: poliomyelitis 116, polio-encephalitis 21. The total number in the thirteen weeks ended March 27, 1948, was: poliomyelitis 425, polio-encephalitis 21. The figures for 1948 were higher than is usual in the first quarter, and the Chief Medical Officer of the Ministry of Health pointed out (*Ann. Rep. for 1938*, p. 32) that a similar phenomenon had been observed in 1927 following the high prevalence of 1926. In 1927 it was attributed to the abnormally mild weather that characterized the last two months of 1926, but in the winter

of 1938-9 there was a very cold spell about Christmas followed by a very wet and cold January.

The incidence of poliomyelitis in the early part of a year seems to be an inconsistent guide to the probable incidence during the year. The following are some examples:

Notifications (Poliomyelitis only)

Year	First quarter	Whole year
1925	72	371
1926	55	1,159
1938	71	1,489
1939	116	744
1944*	58	464
1945	52	784
1946	83	606
1947	102	7,350†

* Figures for 1944 and after are "corrected."
† Estimated "corrected" figure.

Discussion of Table

In England and Wales infectious diseases were less prevalent during the week. There were decreases in the incidence of measles 726, whooping-cough 701, scarlet fever 321, acute pneumonia 243, dysentery 34, and diphtheria 19.

The largest decreases in the incidence of measles were reported from London 291, Middlesex 202, Norfolk 141, and Cheshire 115; the largest increases were Lancashire 131, Derbyshire 95, and Surrey 84. The notifications of whooping-cough fell in all areas except in Wales, where a small rise of 27 was recorded; the largest declines were Middlesex 106, Lancashire 78, Essex 73, Yorkshire West Riding 66, London 54, and Kent 52. The incidence of scarlet fever fell throughout the country; the largest fall was 77 in Lancashire.

Diphtheria was at the lowest level for seven months, although no change of any size occurred in the local trends during the week. A decrease in the number of notifications of acute pneumonia was recorded in most areas; the largest decline was Lancashire 53.

A further 22 cases of dysentery were notified from the outbreak in Derbyshire, Shardlow R.D., where 9 cases were reported last week. The other important centres of dysentery were Lancashire 59 (Liverpool C.B. 17, Salford C.B. 13), Yorkshire West Riding 18 (Sheffield C.B. 13), London 10. The largest returns of acute poliomyelitis were: London 3, Wiltshire (Trowbridge U.D. 2), and Warwickshire (Birmingham C.B.) 2.

In Scotland a decreased incidence was recorded for measles 136, acute primary pneumonia 69, scarlet fever 41, and cerebrospinal fever 15. The only increase was in the incidence of dysentery 23. The chief centres of dysentery were the cities of Dundee 10, Edinburgh 16, Glasgow 9.

In Eire the only changes in the trends of infectious diseases were decreases in the notifications of measles 13 and diphtheria 5, and an increase of 12 in the notifications of diarrhoea and enteritis.

In Northern Ireland the largest changes in trends were a decrease of 20 in the notifications of scarlet fever and an increase of 6 for cases of whooping-cough.

Quarterly Returns for Eire

The birth rate during the December quarter was 202 per 1,000, being 0.5 below the rate for the preceding fourth quarter. Infant mortality was 64 per 1,000 registered births and was above the rate for the December quarter of 1946. The death rate was 11.7 per 1,000; this rate was 0.8 below the rate for the preceding fourth quarter, which was the lowest of the December quarters. The death rate from respiratory tuberculosis was 8 per 10,000 and from other forms of tuberculosis 2 per 1,000; these rates were the same as for the preceding fourth quarter.

The provisional figures for the year show a birth rate of 23.1, the highest of recent years. The death rate was 14.9, being 1.0 above the rate for the preceding year. Infant mortality was 67, being 4 above the rate for 1946. Deaths from infectious diseases included 734 from diarrhoea and enteritis under the age of 2 years, 291 from whooping-cough, 106 from measles, 55 from diphtheria. There were 2,796 deaths attributed to pulmonary tuberculosis and 838 to other forms of tuberculosis—240 and 61 respectively more than in the preceding year.

Week Ending April 3

The notifications of infectious diseases in England and Wales during the week included: scarlet fever, 142; whooping-cough 2,639, diphtheria 161, measles 10,874, acute pneumonia 764, cerebrospinal fever 51, acute poliomyelitis 17, dysentery 188, paratyphoid 1, and typhoid 5.

No. 13

INFECTIOUS DISEASES AND VITAL STATISTICS

Print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended March 27.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) (c) (administrative county), (d) Scotland, (e) Eire, (f) Northern Ireland. *Figures of Births and Deaths, and of Deaths recorded under each infectious disease, or:* (a) The 126 great towns in England and Wales (including London), (b) (c) (administrative county), (d) The 16 principal towns in Scotland, (e) (f) 13 principal towns in Eire, (g) The 10 principal towns in Northern Ireland. dash — denotes no cases; a blank space denotes disease not notifiable or return available.

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ The number of deaths from poliomyelitis and poliomyelitis for England and Wales, London (administrative county), are combined.

§ Includes paratyphoid fever for England and Wales and Eire.

Medical News

Mrs. Roosevelt at Netherne Hospital

On Friday, April 9, Mrs. Roosevelt visited Netherne Hospital, Coudsdon. She saw the chapel, nurses' training school, female occupational therapy department, the patients' canteen, the staff and patients' cafeterias, the insulin bay, operating theatre, art studio, three of the reception wards, library and reading room, hairdressing saloons, laboratories, a display of occupational therapy, and an exhibition of the patients' pictures. Mrs. Roosevelt was particularly interested in radiography taken during leucotomy operations with two leucotomies in position in the brain. The charts of cases she saw undergoing prolonged narcosis were inspected and she asked many questions about the nursing and feeding. The gallery of pictures which had been produced in psychotherapeutic sessions also attracted Mrs. Roosevelt's attention, particularly as she had some knowledge of the use of this work in the treatment of delinquent children. The various kitchen articles, toys, and library shelving made from salvage material were carefully examined as were some of the occupational products which are being sent to America through the Women's Voluntary Services. Mrs. Roosevelt asked about the social work of the hospital, the follow-up scheme, the patients' social clubs, the willingness of patients to return if they became well, the patients on ground and town parole, the admission rate, and the hospital population. A number of the Women's Voluntary Service workers who have given welcome assistance in the hospital for the past two years were introduced to Mrs. Roosevelt.

Research in Disseminated Sclerosis

A gift of money has enabled the Middlesex Hospital Medical School to endow a scholarship for research in organic nervous diseases. The work will be carried out under the direction of the physician in charge of the Department for Nervous Diseases. The subject chosen for research is disseminated sclerosis. Dr. N. D. Compston, M.R.C.P., has been appointed research scholar for 1948-9.

Health Education

The Central Council for Health Education is planning regional courses of lectures to be held throughout the country for professional workers nominated by local authorities. Attendance is free. It will also appoint an exhibitions officer to make material available free of charge for exhibition by local health authorities. In order to develop these services the Central Council has closed down its area offices except in Northern Ireland. Information may be obtained from the Central Council, at Tavistock House, Tavistock Square, London, W.C.1.

American Psychiatric Association

Dr. Daniel Blain, formerly chief of Neuropsychiatric Services for the Veterans Administration, has been appointed Medical Director of the American Psychiatric Association.

Chevalier of the Order of St. Charles

The decoration of Chevalier of the Order of St. Charles has been conferred upon Dr. Kenneth Edward Eckenstein by the Prince of Monaco, in recognition of valuable services rendered by him in the capacity of Vice-Consul at the Consulate-General of Monaco in London.

Wills

Lieut.-Gen. Sir Harold Ben Fawcett, K.C.B., C.M.G., D.S.O., formerly D.G.A.M.S., left £838. Dame Freda Clara Martyn, formerly Dr. Freda Kelly, widow of Sir Henry Martyn, K.C.V.O., left £2,533. Dr. John Edridge Healey, of Fulwood, Lancs, left £66,373. Surgeon Rear-Admiral Charles Marsh Beadnell, president of the Rationalist Press Association, left £7,733.

COMING EVENTS

Exhibition of German Publications.

Lord Pakenham, Minister for Germany and Austria, will open the first post-war exhibition of German publications from the four zones of occupation at the Academy Hall, Oxford Street, London, W., on Monday, April 19, at 4 p.m. The exhibition will remain open for a week.

South-West Metropolitan Region Psychiatric Advisory Group

A general meeting of the psychiatrists in the South-West Metropolitan Region will be held at the County Hall, Kingston-upon-Thames, on Wednesday, April 21, at 5 p.m. The chairman of the Regional Board, Mr. F. H. Elliott, D.L., J.P., has kindly invited all those attending to tea at 4.30 p.m. Those who intend to be present should notify the honorary secretary, Dr. T. P. Rees, Warlingham Park Hospital, Warlingham, Surrey.

Lebanon Hospital for Mental Diseases

The 48th annual meeting of the Lebanon Hospital for Mental Diseases will be held at the Cora Hotel, Upper Woburn Place, London, W.C., on Thursday, April 22, at 4.30 p.m., when the medical director, Dr. R. B. Robertson, will present his first annual report and personal accounts of the work of the hospital will be given by Mr. R. de C. Baldwin and Dr. W. M. Ford Robertson. There will be opportunity for questions and discussion and all interested are invited to attend the meeting.

Association of Surgeons of Great Britain and Ireland

The annual meeting of the Association of Surgeons of Great Britain and Ireland will be held at Edinburgh on Thursday, Friday, and Saturday, May 6, 7, and 8, instead of in July as previously planned. A full programme will be circulated in April, but the provisional arrangements are as follows: *May 6*, business meeting; discussion on "Maintenance of Metabolism by Parenteral Methods." *May 7*, discussion on "Diaphragmatic Hernia." *May 8*, discussions on "Hypertension" and "The Surgery of Pancreatic and Ampullary Neoplasms." Fellows or Associate Fellows requiring accommodation in Edinburgh should apply direct to Messrs. Thomas Cook and Son, Ltd., Princes Street, Edinburgh (Tel. Edinburgh 33794), as soon as possible. There will probably be a meeting of the International Surgical Society on May 6 at 5 p.m. Fuller details may be obtained from Mr. H. W. S. Wright, M.S., F.R.C.S., honorary secretary of the Association, at 45, Lincoln's Inn Fields, London, W.C.2.

N.A.P.T. Medico-Social Section

The Inaugural Meeting of the N.A.P.T. Medico-Social Section will be held on May 7 at 5 p.m. at B.M.A. House, Tavistock Square, London, W.C.1. Sir Robert Arthur Young will preside, and Mr. Anthony Greenwood, M.P., will address the meeting on "Social Aspects of Tuberculosis." All who are interested in social work for the tuberculous are invited.

Haematology

The International Society of Hematology will hold its biannual meeting at the Hotel Statler, Buffalo, New York, on Aug. 23-26. Those interested should communicate with Dr. Robert R. Race, Lister Institute, Chelsea Bridge Road, London, S.W.1.

Physical Education

The Friends of Physical Education will hold an International Congress at Venice on May 10-13. Further information may be obtained from Prof. Mario Gallo, Comitato Esecutivo di Feste Internazionali di Educazione Fisica e Sports, Venezia, Italy.

International Congress on Obstetrics and Gynaecology

The American Committee on Maternal Welfare has agreed to sponsor, in conjunction with the Fourth American Congress, a conference on obstetrics and gynaecology, which will be held at Hotel Pennsylvania, New York City, from May 14 to 19, 1950. All inquiries should be addressed to the general chairman of the congress, Dr. Fred L. Adair, 24, West Ohio Street, Chicago 10, Illinois, U.S.A.

Climatology

An International Congress of Climatology and Thalassology will be held at Riccione (Forlì), Italy, on June 12-13. Further information may be obtained from Prof. Tommaso Oliaro, Minerva Medica, Torino, Italy.

Airborne Medical Services

All ranks who served in the 1939-45 war who wish to attend a reunion of the Airborne Medical Services on or about Sept. 25 in or near London should communicate with Major A. D. Young, D.S.O., R.A.M.C., The Depot and T.E., R.A.M.C., Boyce Barracks, Crofton, Hampshire.

SOCIETIES AND LECTURES**Saturday**

BRITISH ASSOCIATION OF ALLERGISTS—April 17, 11.30 a.m., at Junior Common Room, Worcester College, Oxford, Business Meeting. 2.30 p.m., at Lecture Room, Nuffield Institute of Medical Research, 43, Woodstock Road, Oxford, Scientific Meeting and Discussion, "Allergic Conditions of the Eye." One speaker, Dr. Vera Walker.

BRITISH CLINICAL MEDICAL SOCIETY—At Shewley Hospital, near St. Albans, Herts., April 17, 3 p.m., General Meeting. *Demonstration of the use of the Electro-Cardiogram in Therapy and Curative.* Dr. D. W. Shepherd and Dr. D. T. Barton followed by Dr. R. Pratt and Dr. S. T. Hayward.

Monday

EDINBURGH UNIVERSITY: PHYSIOLOGY CLASSROOM—April 19, 11.30 a.m., "Medical Archaeology and Folklore," by Dr. Douglas G. Hunterian Society.—At Talbot Restaurant, London W.C.1, April 19, 7 for 7.30 p.m. Annual general (dinner) and "Laboratory Animals—Their Uses and Abuses." Address by Mr. A. L. Bacharach.

ROYAL SOCIETY OF ARTS, John Adam Street, Adelphi, W.C.—April 19, 4.30 p.m. Second Cantor Lecture on Advances in Anaesthesia: "The Theory of Anaesthesia and Chloroform—Early Apparatus—Inhalation Anaesthesia—Signs of Anaesthesia. The Anaesthetic Gases—Apparatus." Dr. Frankis T. Evans.

Tuesday

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE—At Edinburgh Royal Infirmary, April 20, 5 p.m. "Medico-Sociological Aspects of Marriage," by Prof. F. A. E. Crew, F.R.S.

Wednesday

HARVEIAN SOCIETY OF LONDON—At St. Mary's Hospital, Paddington, W., April 21, 4.15 p.m. Clinical Meeting: "Penicillin Doses," by Sir Alexander Fleming, F.R.S.

ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE, 28, Portico Place, London, W.—April 21, 3.30 p.m. "The Influence of Heredity on Disease (Illustrated)," by Prof. L. S. Penrose.

Thursday

EDINBURGH ROYAL INFIRMARY—April 22, 4.30 p.m. Illegible Lecture: "Folic Acid—Indications and Contraindications," by Prof. L. S. P. Davidson.

MEDICO-LEGAL SOCIETY—At 26, Portland Place, London, W., April 22, 8.15 p.m. "The Medico-Legal Problems of the Doctor," by Sir Geoffrey King and Dr. J. H. Sheldon.

Saturday

KENT PAEDIATRIC SOCIETY—At the Star Hotel, Maidstone, Kent, April 23, 2.30 p.m. Annual general meeting.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, Chandos Street, London, W.—April 24, 2.30 p.m. General meeting. "The History of the Treatment of Venereal Disease," by Mr. Johnston Abraham.

BIRTHS, MARRIAGES, AND DEATHS**BIRTHS**

Anderson—On March 28, 1948, to Tessa, wife of Dr. A. L. S. Anderson, Hill, Littleborough, Lancs., a son.

Brittain—On April 1, 1948, at Harcourt Nursing Home, Dublin, to the wife of Dr. George Brittain, a son.

Buxton—On March 14, 1948, to Alysion, wife of Dr. Robert James F. Galhampton Manor, Yeovil, Somerset, twins—son and daughter.

Cohen—On April 4, 1948, at Westminster Hospital, to Joan (née Eshel) of Dr. E. G. Cohen, a daughter—Diana Gillian.

Cooper—On March 20, 1948, at Southmead Hospital, Bristol, to Flora G. (née James), M.B., Ch.B., D.A., wife of Ashley Cooper, a daughter—Lisa.

Fodden—On April 5, 1948, at Park House, Waterloo, Liverpool, to the wife of Dr. J. H. Fodden, a daughter.

Grant—On March 24, 1948, at Gwyn-mor Nursing Home, Cardiff, to the wife of Hugo M. Grant, M.B., Ch.B., F.R.C.S.Ed., a son—Ian Nicholas.

Hendry—On April 2, 1948, at Nuneaton General Hospital, to the wife of D. W. Hendry of Nuneaton, a son—A brother for Billy and Ian.

Kershaw—On March 25, 1948, at 51, Lillingston Road, Leamington Spa, to Valerie (née Jackson), wife of Dr. G. R. Kershaw, a son.

McConachie—On April 2, 1948, to Dorothy J. McConachie (née Macdonald), M.B., Ch.B., wife of James S. McConachie, M.B., Ch.B., F.R.C.S., 11, Burnside Gardens, Aberdeen, a son—Stewart.

McNally—On March 28, 1948, at Dublin, Eire, to Betty (née Harty) of P. A. McNally, M.D., F.R.C.P.I., a daughter.

Williams—On March 25, 1948, at Firs Maternity Hospital, Newcastle, to Margaret Doreen (née Shaw), wife of Dr. T. Gwynne Williams, a son.

MARRIAGES

Stevenson-Ferguson Wood—On Feb. 26, 1948, at Addiscombe, Surrey, Stevenson, M.R.C.S., to Marjorie Ferguson Wood, B.Sc., S.R.N.

Way-Cattermole—On April 3, 1948, at Christ Church, Radley, Oxford, Way, M.B., B.S., (London), to Jean Cattermole, S.R.N.

DEATHS

Blair—On April 1, 1948, at 16, Greyfriars Gardens, St. Albans, Herts., Edward Blair, M.D.Ed.

Brown—On March 28, 1948, at Llanynhafal, Denbigh, N. Wales, Brown, M.B.E., M.B., Ch.B., aged 68.

Calthrop—On April 7, 1948, Gordon Thomas Calthrop, M.D., D.P.H., M.D., F.R.C.S., aged 82.

Gandy—On March 30, 1948, at Corners, Ceme Abbas, Dorset, Gandy, M.B.

Harker—On March 31, 1948, at St. Thomas's Hospital, London, SE 1, Vaughan Harker, M.R.C.S., L.R.C.P., D.P.M., aged 72.

Philpotts—On March 26, 1948, at "Seaward," The Rectory, Northumberland, George Robert Philpotts, M.D., B.S., aged 72.

Pollock—On March 22, 1948, Aileen Marion Scott Pollock, B.Sc., Principal, Women's Christian Medical College, Edinburgh, aged 52.

Rehder—On March 20, 1948, at his home, 1, Market Street, Brighton, Christopher Joseph Rehder, M.R.C.S., L.R.C.P.

Any Questions?

respondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Liquid Paraffin for Cooking

Q.—The use of mineral oil for consumption and for cooking purposes seems to be increasing. Apart from the fact that the oil is wholly without food value, has it or has it not any deleterious effect upon the consumer? In the United States, opinion is held that the use of mineral oil in salad dressing is an adulteration under the Federal Food, Drugs, and Cosmetic Act, however it may be labelled. A recent decision in a North-East of England magistrates' court confirmed this opinion, and evidence was given that the continued use of hydrocarbon oil might lead to a "paraffin liver." Is there any evidence to support these opinions?

A.—The laxative properties of mineral oil (liquid paraffin) depend upon the fact that it is almost completely unabsorbed, the possibility of its leading to "paraffin liver" seems hardly likely to arise when the cells of the intestinal lumen are exercising their normal physiological functions. These generally do not allow the passage of particulate fat unless the globules are below a certain critical diameter, depending upon a number of factors, including the chemical nature of the fat itself. If, however, circumstances favour the thorough dispersion of liquid paraffin in the upper part of the alimentary tract there may occur some degree of absorption, with subsequent storage there in the fat depots along with unsaponified fats via the lymphatics, or in the liver along with resaponified fatty acids in the portal vein. It is conceivable that continuous treatment with relatively high doses of paraffin might therefore ultimately lead to considerable deposition in the liver, though it is doubtful what pathological consequences, if any, would follow.

There is, however, one clear contraindication against the excessive oral use of mineral oils. At the present time a considerably higher proportion of our vitamin A requirements is being met by the conversion of vegetable carotenoids (particularly β -carotene) into vitamin A than by supplies of the pre-formed vitamin, restricted owing to the relative shortage of eggs, milk, cheese, and liver, which were the most abundant sources in pre-war diets. Carotene is a hydrocarbon, vitamin A is an alcohol, with the result that the former is the more lipophilic and the latter the more hydrophilic. Consequently, in an emulsion containing both carotene and vitamin A the carotene will tend to pass into the non-aqueous and the vitamin A into the aqueous phase. If the non-aqueous phase consists of a considerable extent of unabsorbable oil, such as liquid paraffin, it is clear that a corresponding proportion of the provitamin will be lost in the faeces with the oil. The greater the proportion of vitamin A derived from the provitamin in the diet the more likely is excessive paraffin medication to reduce some degree of vitamin-A deficiency. This medication should, in all instances, be taken in moderation; its use as a substitute for vegetable oils in salad creams and cooked products generally should be prohibited by law; and the rare cases requiring unusually large doses should be recommended to take between these doses some concentrated preparation of vitamin A, of which a number are available through ordinary channels.

Stability of Penicillin

Q.—How long do the various preparations of penicillin retain their potency? Could an authoritative table be given for ordinary penicillin, crystalline, ointment, cream, lozenges, emulsion, solution in saline—both at ordinary room temperature and when stored in the usual household refrigerator?

A.—The stability of penicillin depends on its degree of purity, concentration, and composition, and on the pH of the medium in which it is contained and temperature. Although there is much accurately determined and published information about the rate

of deterioration of different preparations, so many variables are concerned that no hard-and-fast rules are possible. The powder itself is indefinitely stable if kept dry, but according to Brindle and Keefe (*Quart. J. Pharm.*, 1947, 20, 177) the usual commercial type of container capped with rubber is not efficiently sealed against moisture; this can slowly enter and cause loss of potency. Other dry preparations, such as lamellae and lozenges, should keep for months if protected from the air. Properly made solutions deteriorate slowly in a refrigerator. A satisfactory rule would be to use them within one week. Ointments or creams, if the base is satisfactory, behave similarly. Since exact potency is less important, they might well be kept for longer periods in the cold. At room temperature deterioration is more rapid. Solutions and creams should be refrigerated unless they are to be used up within two days.

Immunity to Cancer

Q.—(a) Is there such a thing as natural immunity to cancer in human beings? (b) Has any lysis or agglutination been observed when the serum of a healthy person whose family is known to be free from cancer is brought into contact with living human cancer cells? (c) Have blood or plasma transfusions from healthy persons of non-cancer families been tried in the treatment of human cancer?

A.—(a) So far as is known, no condition of natural immunity to cancer is found in man. Since it might be difficult to demonstrate, this is not to say it does not exist, and remarkably high degrees of insusceptibility, either to particular classes of tumour or to spontaneous cancer as a whole, can be attained by selective inbreeding in mice. Even so, such animals may be susceptible to the induction of cancer by a carcinogenic agent applied externally. Apart from natural immunity, organ immunity may be conferred in special cases by intervention, notably in cancer of the penis, which does not occur after circumcision on the eighth day according to the Jewish practice. It should be noted that the protection given by the Jewish operation is not due to removal of the cancer-bearing area (see Kennaway, *Brit. J. Cancer*, 1947, 1, 335).

(b) Lysis of live cancer cells by normal serum was described by Freund and Kaminer, and was made the basis of the so-called Freund-Kaminer diagnostic reaction, which, however, has not been generally confirmed.

(c) The writer is not aware of any such attempts except those undertaken from time to time in leukaemia, and most recently by P. Croizat and L. Revol ("Traitement des leucémies aiguës par les perfusions sanguines répétées," *Lyon méd.*, 1947, 177, 553-60). In such cases transfusion is of course carried out using blood from healthy persons, not necessarily "of non-cancer families."

Massage in Spastic Paralysis

Q.—Does massage influence muscle tone? What is the value of massage in the affected limbs in: (a) spastic paraplegia of cerebral origin; (b) spasticity of striatal disease; and (c) compression paraplegia of traumatic origin?

A.—Massage does not influence muscle tone. The three types of spastic paralysis mentioned respond similarly to massage and need not be considered separately. While physiotherapeutic techniques such as muscular relaxation and re-education can be most helpful, massage alone is not likely to be of value in these conditions. Superficial effleurage expertly administered may assist in obtaining relaxation prior to re-educative exercises, but massage wrongly applied may act as a stimulus to further muscle contraction.

Diet after Total Gastrectomy

Q.—Can you advise a suitable diet for a man who has had a total gastrectomy?

A.—Most patients who have undergone total gastrectomy can take a diet of the post-Lenhartz type. In the early stages multiple small meals at regular intervals are desirable; these may include pounded fish, minced meat, and purées of vegetables as well as the other dishes which are common to all diets for convalescence from peptic ulceration. The proximal loop of jejunum rapidly becomes dilated and able to accommodate a meal of reasonable size without discomfort to the

patient. Nevertheless it is advisable to avoid bulky foods, and the caloric value of the diet must be maintained with milk drinks. There is need for additional vitamins, and this is best met by giving a concentrate. Such patients also have particular difficulty in absorbing iron.

Early Signs of Rheumatoid Arthritis

Q.—Is a vague generalized stiffness of the muscles on getting up in the morning an early sign of rheumatoid arthritis? If so, what treatment should be undertaken? The case in question is that of a woman of 35 whose mother developed rheumatoid arthritis at the same age after the same early symptoms.

A.—The symptoms in this case cannot be regarded as definite signs of early rheumatoid arthritis, but in view of the family history they call for careful investigation and close observation. The sedimentation rate should be taken, and repeated possibly at monthly intervals for a time, together with blood counts, morning and evening temperatures, and search for any possible infective focus. The only other treatment at this stage should be by general tonics, and especially cod-liver oil. There may be a nervous factor in the form of fear of arthritis, and reassurance must be emphatic if the investigations are negative. Contributory influences, over-fatigue, deficient nutrition, worry, and anxiety must also be guarded against so far as is possible.

Curly Hair and Pregnancy

Q.—Since the birth of my first child six months ago my hair seems to have lost its former natural curl. Is the curl likely to return, as there is no sign of it so far? If I were to have a "permanent wave" would it have an adverse effect on any natural tendency to curl which is at present dormant?

A.—After the birth of a child it is quite usual for the hair to change character entirely. This is due to the endocrine rearrangement natural after pregnancy. Any patient in whom such a change is marked ought to be medically examined for evidence of endocrine dysfunction and treated accordingly. As a rule small doses of thyroid and large doses of vitamin B (whole complex) should aid the return to normal. If the normal periods have not been resumed oestrone may be indicated. A permanent wave carried out by the hot method would have no adverse effect on the natural tendency to curl. The waving must be done by a skilled operator, so that no over-drying effect is caused.

Autoserotherapy in Allergy

Q.—In the treatment of allergic skin eruptions I have been advised to inject the patient's own blood intramuscularly in doses of from 1 to 12 ml. Is it as effective to take off a pint of blood, store it, and give the serum in graduated doses?

A.—Autoserotherapy subcutaneously is usually considered as effective as and essentially the same as intramuscular autohaemotherapy. The treatment is empirical, and roughly the same amount of serum as of whole blood is used.

Mechanism of Rigors

Q.—What is the productive mechanism of a rigor? What agents may produce a rigor?

A.—The causes which initiate the train of events termed a "rigor" are ill-understood. It is generally held that the pyrogenic agents act directly or indirectly on the heat-regulating centres, for they are without effect in decerebrate animals. Another suggestion is that the locus of the action of these substances is peripheral, causing a flow of water from the vascular system to the tissues, with consequent reduction in the circulating blood volume and a decrease in cutaneous blood flow which initiates the nervous mechanism. Whatever may start the process, the earliest obvious change is cutaneous vasoconstriction, which, by reducing heat loss from radiation and convection, causes the body's temperature to rise. The sensation of warmth and cold depend on the skin temperature, which is a function of the blood flow through the superficial vessels. Cutaneous vasoconstriction thus results in a sensation of warmth, although the internal temperature of the body is actually raised. The fall in skin temperature evokes the reflex which usually raises the body's temperature in such

circumstances: this is the fine fibrillary contraction of skeletal muscles, experienced as shivering, with contraction of the smooth muscle to cause "goose flesh." Thus increased heat production is added to reduced loss, and the body's temperature rises rapidly. When it reaches a level which varies from case to case there is sudden relaxation of the cutaneous vasospasm, the skin flushes, and as the warm blood floods through the superficial vessels the patient's sensations change to those of intense heat. Heat loss by radiation and convection is greatly increased at this stage and may be further aided by evaporation of the profuse sweat which may bathe the body surface. In patients with such disorders as malaria the changes are sufficient to reduce the body temperature to normal in an hour or two; where a rigor initiates a period of continuous fever sweating is absent, but a balance between heat production and heat loss is struck, so that the body temperature is maintained at a constant, though higher, level.

Among the infective agents which produce rigors are certain bacterial "toxins," particularly those of the pyogenic cocci, the *coli* group; the malarial parasites; the rickettsiae; *Leishmania donovani*. Although rigors are less common in infections due to viruses, they occur frequently at the onset of smallpox, sandfly fever, and influenza. Injection of foreign protein, particularly when intravenous, is followed by a rigor if the dose is large enough. The rigors which follow infusion of saline or blood transfusion are to be attributed to pyrogens elaborated by bacteria contaminating the distilling water. Certain non-protein agents, especially those containing sulphur, have a similar effect.

Phlebitis in the Leg

Q.—What is the best treatment for the phlebitis in the leg so often seen in middle-aged women? Has penicillin proved to be of any use in this condition?

A.—Penicillin has been found to be of no value in any form of phlebitis except the suppurative or the septic type, which is invaluable. Recurring phlebitis in middle-aged women usually occurs in varicose veins, and these should be treated radically by simultaneous ligation and injections if the patient is not too obese or the phlebitis is not part of a severe thrombotic tendency. The active attacks should be treated with "elastoplast" support supplemented by padding above and over the actual clots. Dicoumarol therapy is also indicated during attacks, and very quickly brings them under control.

NOTES AND COMMENTS

Pyloric Stenosis.—Dr. T. N. NAUTH-MISIR (Brentwood, Essex) writes: I notice that in answer to a question on the use of atropine nitrate in the treatment of congenital pyloric stenosis ("Any Questions?" March 20, p. 583) you state that a 0.6% solution in alcohol are required to 1 ml. of the 1 in 10,000 solution. I would like to point out that this is inaccurate. One drop of the 0.6% alcoholic solution is 0.1 mg. of methyl atropine nitrate (*Textbook of Paediatrics*, p. 621. Edited by Waldo E. Nelson. W. B. Saunders and Philadelphia), and 1 ml. of the watery solution also contains 0.1 mg. Therefore one drop of the former is equivalent to 1 ml. of the latter. Absorption of the alcoholic solution occurs as soon as the drop is placed on the infant's tongue, unlike the watery solution which takes a little while to dissolve. For this reason I think the alcoholic solution is to be preferred. The initial dose of 2 drops placed on the tongue twenty minutes before each feed may be increased to three or four drops if necessary, rarely necessary to exceed four drops.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY APRIL 17 1948

THE NEW ZEALAND SCHEME

annual meeting of the New Zealand Branch of the British Medical Association was held on Feb. 3, when Mr. J. A. Sims, President of the Branch, spoke on the medical service suggested some remedies for the abuses to which it is put.

He said that the public had paid very dearly for a service naturally felt entitled to get it. That applied to both hospital and private medical services. No one could demur at that, though it could be pointed out that a service had been sold that did not belong to the seller, and that there had been a promise of hospital facilities that did not exist.

The majority of the population was fair-minded and reasonable, but from both observation and conversation it was evident that there was a section sufficiently abnormal to look for visits to a doctor as one of life's interests, who enforced formalities knowing that they could go from door to door until an impecunious doctor was reached. It could logically be said the doctor was to blame, but in the present service the more meritorious the medical man the larger his practice and income became. There was something very wrong in such a system.

More serious than the waste and cost was the deleterious effect on the medical man, who was forced by circumstances to be a party to what he inwardly knew to be humbug, at times bordering on fraud. It was humiliating to the extreme degree, and eventually must lead to an outlook that changed him from a conscientious to a form-signer. Laws had been passed that were obviously parallel with those either in operation or hoped for by Labour Governments in many countries. It was no overstatement to say that the underlying objective was for a political

in their discussions with the Government in 1937 and 1938 weaknesses in the structure of the scheme had been pointed out.

These were the defects of to-day. It was his conviction that if their memorandum of December, 1937, had been tried and developed they would have had a service free of most of the present defects and abuses. Perhaps it was not too late.

There was a way out of the present difficulty. Medicine and tactics would never mix, irrespective of the political party or period. The Department of Health should cover hygiene, preventive medicine, and the control of infectious diseases, but not be suited to the task of operating a medical service. The Government should appoint a permanent commission completely free of all political influence to control all hospital health services. If the key personnel were wisely chosen and possessed of real authority, success should be assured. The requirements were a commissioner trained in administration, impartial, broad-minded, well educated, with the integrity of a judge, assisted by a commission made up of representatives of all employed in the work, nominated by them and appointed by the Government from the nominations submitted. The second point would be a reorganization of health and hospital districts, each area being controlled by a regional committee which would be advisory to the commission and have advisory powers in its own area.

It was probable that the Dominion was training almost twice the number of students required by the population, and there was but little incentive now for graduates to go on to higher degrees or diplomas.

They were living on their capital so far as highly trained men were concerned, and unless the situation changed they

would become a country in which all had been levelled to mediocrity. There must be no compromise with a system predestined to lower the standards.

If the Government had the courage to admit it had misjudged human nature, both as regards the public and the profession, and placed a small financial barrier between the patient and doctor, patient and chemist, and patient and hospital, many of the present abuses would cease at once.

The Minister of Health, Miss Howard, addressed the conference on Feb. 4 on the general practitioners' scheme, saying that, though it had for the most part fulfilled its purpose, there nevertheless were some defects. The great majority of their doctors continued to practise as they would under conditions of ordinary private practice. They had considered it beneath them to give other than the best that their knowledge, experience, and their ethical standards fitted them to give. A few, on the other hand, were undoubtedly exploiting the scheme. The mere number of attendances, for each of which they received a standard fee of 7s. 6d. from the Social Security Fund, was, one could only suspect, their chief measure of the service they could render the community.

There were only very limited and unreliable means of finding out who were the black sheep. The Department could see what amounts were paid from the fund to every doctor, together with the amount of refunds made in respect of attendances by them. Although it was an incomplete picture, it was a matter of no little concern that for 232 doctors, or approximately 20% of the total, payments or refunds for last year had exceeded £3,000. A number of them in this category were men of outstanding skill and reputation, and it was not with them that they were concerned. Three of them had exceeded £10,000.

It was common knowledge and a source of considerable gratification that the great bulk of the profession were equally concerned with the consequences of inordinate payments from the fund. It was most heartening, therefore, that through the good offices of the Council it had been possible to set up a joint committee of representatives of the Association and the Department to examine the working of benefits in respect of medical services.

Another matter which had also given them concern, and one which the Association was already moving to correct, was the excessive charges on the fund for pharmaceutical benefits. Not only had the number of prescriptions shown a striking upward trend, but the Department had drawn attention on several occasions to a tendency on the part of a few doctors to prescribe unduly costly drugs.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar.

Non-Country Borough Councils.—Dartford, Radcliffe (limited to future appointments), Tottenham, WallSEND.

Urban District Councils.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Portslade, Redditch (restricted to new appointments), Tyldesley.

Scottish Burghs.—Motherwell and Wishaw.

HEARD AT HEADQUARTERS

Organization of Consultants

The organization of the new Regional Consultants and Specialists Committees is a piece of Association work in connexion with any new health service which will be of permanent value. These committees with the central committee at Headquarters will represent all consultants and specialists on the most democratic basis. They will help to prevent the chief danger which those who are concerned with the hospital problem see in the new regional set-up—namely, the separation of the teaching hospitals from the ordinary regional hospitals. This danger was voiced at a recent meeting at the Royal Society of Medicine which was addressed by several of those who took part in the Hospital Surveys inspired by the Ministry of Health. The committees, representing all consultants whatever their attachment, and whether teaching or non-teaching, whether in the employment of local authorities or in private practice, will help to prevent that rift. Of course, if there is any real divergence of interest it will still be possible for subcommittees representing teaching interests and non-teaching interests to be formed, but they will all be within the new framework and will be identified with the general body of consultants, just as the regions themselves will be linked up into one through the central committee.

The Association's Film Library

A great deal of work, some of it highly expert, has been put in by the Film Committee of the Association, and the Film Bureau and Library is now well in sight. A projector is to be purchased so that films can be viewed at B.M.A. House or at medical meetings elsewhere, and the next task is an appraisal of the films already in the Association's possession and other films provided or recommended from other sources. When these films have been assessed it will be necessary to make a number of copies of those to be included in the library. The films will be only those that meet the requirements of medical audiences. Many films on medical subjects, of course, have no particular value for members of the medical profession, and to extend the scope to cover health films in general would be to enter a very wide territory with results perhaps of little value from the objective which the Film Committee has been pursuing. The Association's Film Library will be complementary to rather than in competition with the Central Film Library of the Central Office of Information, and indeed some of the films which are not considered of use for medical audiences may be passed on to the Central Film Library.

FEEs FOR MIDWIFERY

The Minister of Health has prescribed a new scale of fees for medical practitioners called in by midwives. They come into operation on April 18. The Minister points out that the medical practitioner must claim his fees within two months by statute, but, recognizing that this may be inconvenient, he intends to propose to Parliament the extension of the time limit.

Scale of Fees

(1) Fee for all attendances of a medical practitioner during the period from the beginning of labour until the child is born, whether or not operative assistance is involved, including subsequent visits to mother and/or child during the first fourteen days inclusive of the day of birth, and including also a post-natal examination at or about the sixth week after the birth, except where owing to circumstances beyond his control the practitioner cannot undertake such examination, £4 14s. 6d.

(2) Fee for all or any of the following—namely, version in labour, removal of adherent or retained placenta, exploration of the uterus, treatment of post-partum haemorrhage or any operative emergency arising directly from parturition, including subsequent visits during the first fourteen days inclusive of the day of birth, and including also a post-natal examination at or about the sixth week after the birth, except where owing to circumstances beyond his control the practitioner cannot undertake such examination, £4 14s. 6d. A fee is not payable under this paragraph when a fee under paragraph (1) is payable.

(3) Fee for a single attendance only, either during the period from the beginning of labour until the child is born (whether or

not operative assistance is involved) or for any of the purposes mentioned in paragraph (2), £2 12s. 6d. A fee is not payable under this paragraph when a fee under paragraphs (1) or (2) is payable.

(4) Fee for either of the following—namely (a) surgery of perineum, (b) resuscitation of baby, £3 3s.: provided that if only one attendance is made a fee of £2 12s. 6d. shall be payable in lieu of the £3 3s. A fee is not payable under this paragraph when a fee under paragraphs (1) to (3) is payable.

(5) Fee for induction of labour whether or not more than one visit is involved, £2 12s. 6d. A fee is not payable under this paragraph when a fee under paragraphs (1) to (4) is payable.

(6) Fee for attendance at, or in connexion with, a case of abortion, miscarriage, threatened abortion, or ante-partum haemorrhage at the 28th week of pregnancy, including all visits in respect of attendance during the fourteen days from and including the first visit, £4 4s.: provided that where only one attendance is made a fee of £2 12s. 6d. shall be paid in lieu of the £4 4s.

(7) Fee for attendance of a second medical practitioner to give an anaesthetic, whether on the occurrence of abortion or miscarriage at parturition, or subsequently, £1 15s.

(8) Fee for visits to mother and/or child not included under paragraphs (1) to (6): Day (9 a.m. to 8 p.m.), first visit, 13s. 6d. subsequent visit, 10s. 6d. Night (8 p.m. to 9 a.m.), 11s.

(9) The usual mileage fee of the district to be paid for all attendances under paragraphs (1) to (8): provided that one mileage only shall be paid in respect of one journey, whether such journey is made for visiting one or more than one patient.

(10) Fee for attendance on mother or child at the medical practitioner's residence or surgery, 5s.

(11) The appropriate fee as prescribed above shall be increased the amount of any reasonable expenses necessarily incurred by the practitioner in supplying any of the drugs or preparations below where such a drug or preparation is essential for the treatment of the mother or her child.

List of Drugs and Preparations

Carbon dioxide,	Penicillin preparations,
Ergometrine,	Pethidine,
Lobeline,	Sex hormones,
Liver extract and injections of liver,	Sulphonamide preparations,
Methylamphetamine,	Vasopressin,
Oxygen,	Vitamin B ₁ complex,
	Vitamin K.

MEDICAL BOARDS

Fees for specialist members of Ministry of Pensions Medical Boards have been the subject of discussion and correspondence since the Ministry's announcement of a revision of the payment for this work on Oct. 1, 1947. A deputation from the Consultants and Specialists Committee, headed by its chairman, A. M. A. Moore, met officials of the Ministry of Pensions recently. As a result agreement has been reached on payment of specialist members of the Ministry's medical boards and the fee has been fixed at four guineas for a session which involves the examination of not less than three cases. A remuneration on a case basis was agreed as £2 12s. 6d. for one case and £3 5s. for two cases. The Ministry of National Insurance has also agreed to similar fees for specialist members of medical boards set up under the National Insurance (Industrial Injuries) Act, 1946.

H.M. Forces Appointments

ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonel W. R. D. Hamilton, O.B.E., to be a colonel and has been granted the local rank of Brigadier.

Lieutenant-Colonel D. F. Pantton, C.B.E., has retired on pay and has been granted the honorary rank of Brigadier.

Lieutenant-Colonels G. E. L. Simons, J. C. Gilroy, J. L. Henson, O. J. O'B. O'Hanlon, D. C. Scott, C.B.E., R. N. Phillips, F. J. Hallinan have retired on retired pay and have been granted the honorary rank of Colonel.

Lieutenant-Colonel R. G. Martin, retired and re-employed, reverted to retired pay on ceasing to be employed and has been granted the honorary rank of Colonel.

Major (War Substantive Lieutenant-Colonel) J. E. Jones, retired receiving a gratuity and has been granted the honorary rank of Colonel.

Majors S. G. M. Lynch, F. King, A. J. Clynne, M. S. W. F. R. W. Scott, O.B.E., and W. F. L. Fava to be Lieutenants-Colonels.

C. P. Stevens, M.B.E., has retired, receiving a gratuity, and has been granted the honorary rank of Lieutenant-Colonel. Captains T. A. G. Reed, S. M. P. Conway, M.C., and J. H. Whitham to be Majors. Captains G. T. Wallace, L. F. Q. MacLaine, and J. N. Darbyshire, to be Captains. Short Service Commissions.—Captains R. T. Kiddie and H. E. E. have been granted Short Service Commissions in the rank of Major. Lieutenants H. Benson, D. A. Bailey, A. M. Ferrie, J. Fry, P. A. Hood, G. L. Hamilton, I. Lamond, G. A. K. P. R. Needham, N. O'Beirn, G. D. Powell, H. F. McElligott, V. G. Miln to be Captains. Lieutenants D. Hamilton and Lazarus, from Emergency Commissions, to be Lieutenants. Captain (Brevet Major) B. Malaher, having exceeded the age limit for recall, has ceased to belong to the Reserve of Officers on account of disability.

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

War Substantive Lieutenant-Colonel (Temporary Colonel) G. J. has relinquished his commission and has been granted the honorary rank of Colonel. War Substantive Majors W. T. Thom and J. McK. Johnstone have relinquished their commissions and have been granted the honorary rank of Lieutenant-Colonel. Specialist Short Service Emergency Commission.—War Substantive Captain A. C. Cunliffe has relinquished his commission and has been granted the honorary rank of Major. War Substantive Captains W. J. Ramsay, M.C., A. W. Patton, J. R. Vollet, D. C. Saehdeva, I. Gurland, W. F. Jepson, T. G. R. Crawshaw, and M. V. Kramer have relinquished their commissions and have been granted the honorary rank of Major. War Substantive Captains D. S. Clark, F. Allen, and R. Love have relinquished their commissions on account of disability and have been granted the honorary rank of Major. War Substantive Captains P. Frankl, C. M. Monro, J. A. P. de Speville, E. W. Ball, R. J. Elsborg, and M. Seifert have relinquished their commissions and have been granted the honorary rank of Captain.

Short Service Commissions, Specialists.—War Substantive Lieutenant-Colonel C. G. Parsons has relinquished his commission and has been granted the honorary rank of Colonel. War Substantive Majors W. R. S. Hutchinson, S. Y. Feggetter, and H. E. S. Pearson have relinquished their commissions and have been granted the honorary rank of Lieutenant-Colonel. War Substantive Captains B. Rogers, P. G. Konstam, J. M. Mallett, E. E. O'Malley, and W. Wyse have relinquished their commissions and have been granted the honorary rank of Major. War Substantive Captains L. P. Loperas, R. J. Cairns, and A. B. McGrigor have relinquished their commissions and have been granted the honorary rank of Major.

Lieutenants L. P. Thomas, E. R. Banner, H. L. Backhouse, T. A. Appleby, G. L. Cantrell, J. Chalom, T. Daly, G. E. Davies, J. McK. Jancan, W. McC. Edgar, D. Fitzgerald, H. E. Floukes, B. H. G. Hayward, J. R. Horler, R. P. C. Handfield-Jones, I. D. Jacobs, A. Kerfoot, S. Levy, J. R. M. Miller, F. R. G. Mellor, M. B. Moore, J. A. S. Metcalf, J. S. Noble, I. W. Payne, M. Roper, R. Smith, W. D. C. Thomas, H. N. Taylor, P. M. de C. Williams, L. Whitmore, T. K. Whitmore, J. N. Walton, C. P. O'Hanlon, C. Jones, C. W. Anderson, A. S. MacVicar, D. L. Griffiths, J. Jolleys, R. T. Towson, D. T. Binns, T. C. Beard, H. E. A. Carson, C. Dryburgh, G. R. Fryers, G. Grant, J. D. Huntley, K. E. Inman, H. Links, P. A. Meehan, C. J. J. Silveira, F. R. Sutherland, J. M. Stowers, W. M. Thomas, D. R. Thomas, Venables, J. C. Sloper, A. H. Pote, K. A. Rowley, J. Ainsworth, L. Armistead, L. W. Bland, R. H. J. Fanthorpe, I. M. Gow, R. Goodwin, H. C. Graham, C. C. Jackman, J. Levy, G. B. L. Laird, L. A. Liversedge, R. D. G. MacLennan, M. C. Pennington, S. Raphael, B. S. H. Storr, E. L. N. Shocion-Sack, W. Staunton, V. R. Wardill, C. J. Williams, J. E. R. B. Williams, G. Yerbury, W. J. Jaslowitz, E. G. G. Roberts, G. H. Carrick, R. H. Gosling, Brown, K. Sinclair, D. W. K. Buchanan, I. S. Bruce, J. A. Bullied, A. J. Barry, D. Clark, A. Cameron, J. D. K. Dawes, C. K. Hefferman, J. S. P. Kerr, C. P. Lowther, H. A. R. Losedale, I. R. Lambah, A. I. MacKenzie, R. J. Walsh, J. McG. McKinnon, R. W. L. Heddle, F. M. Hall, R. C. Humphreys, N. S. Moores, K. E. Marsh, M. B. McEvedy, J. McCollum, J. A. Noblett, K. P. O'Sullivan, H. Parkes, R. Raddock-West, C. Rosen, A. D. Stewart, I. F. Stewart, D. A. Sims, D. C. Simpson, K. M. Shaw, G. Trosser, W. Vant Hoff, L. S. Whyte, A. E. White, M. W. P. Ward, S. Whitfield, G. C. Richards, A. A. Baker, J. R. Baker, H. H. D. Kelly, G. V. S. Wright, J. H. E. Carmichael, J. McLelland, G. C. Mackie, and M. Silverman to be Captains.

To be Lieutenants: J. H. Apsted, A. G. Atkinson, S. Brest, D. W. S. Evans, W. S. R. Fenton, E. C. Fleming, E. Giordani, M. Grant, J. N. Harris-Jones, T. L. Henderson, B. G. Irving, E. Jones, F. Nicholl, E. Roderic-Evans, C. S. Treip, J. R. R. Wray, R. McL. Bain, B. W. Barras, R. I. Bodman, D. D. Cowen, M. H. Daniels, A. J. A. Dawes, K. R. Dempster, A. L. de Silva, A. J. E. Dudington, C. M. Dunlop, D. G. H. Hollis, R. K. Jones, I. L. McKelvie, I. Ranger, R. A. Ryan, J. P. A. MacD. Skene, W. B. Smellie, I. Sober, M. J. Souires, K. L. Williams, R. S. Williams, L. C. Wolfman, W. C. S. Von Reykiewski, J. Aiken, J. K. Anderson, J. B. Bell, S. A. Biggar, F. B. Briggs, E. H. Brown, P. D. Collingwood, A. D. Cook, W. A. J. Crane, I. S. J. Crosbie, C. J. C. Drey, E. Dewshury, B. R. Finlay, J. B. Fox, G. Freeman, G. F. J. Goldard, A. Hand, J. L. Harris, P. M. Higgins, N. Jaswon, H. T. Jones, J. Josephs, A. R. Kirby, D. B. Leaming, S. T. Lunt, G. May,

I. McAlpine, K. A. McCluskey, K. McKay, M. S. Millard, A. R. Muir, D. B. Neilson, C. F. Noon, D. O'Brien, J. B. O'Donovan, M. H. Pettigrew, W. R. Plews, A. I. G. Robertson, L. W. Robinson, A. D. Roy, S. Saehner, N. R. W. Taylor, H. M. Adam, D. K. M. Allison, E. Armitage, W. H. Barker, T. H. Barrie, P. J. H. Barron, M. A. Birnsting, M. D. Blend, I. H. Brave, R. A. Bremner, I. F. Bruce, A. E. Caines, D. J. Cawthorne, W. F. Crane, M. E. Evans, J. P. Fraser, B. A. Gavourin, L. A. Gillanders, D. L. Goughly, A. C. Griffith, D. A. Gregson, A. Guinea, J. S. Happel, C. Hayward, E. V. Hulst, F. G. Isaacs, W. Jack, M. S. Kay, D. Keith, J. G. Kilner, H. F. Lake, N. P. Lancaster, R. A. L. Leatherdale, J. G. Leopold, M. F. Levy, D. C. Lindars, W. H. McIlveen, B. D. McKee, H. M. MacLeod, B. MacTaggart, V. T. Mason, H. G. Parker, D. Refson, S. Solomon, J. Stewart, W. E. Suffield, M. H. Turner, J. C. Ward, R. M. C. Williams, J. H. B. Yule, and D. G. Walker.

HOUSEHOLD CAVALRY

Lieutenant H. W. Trusted to be Surgeon Captain.

WOMEN'S FORCES

EMPLOYED WITH THE R.A.M.C.

War Substantive Captains I. M. Coleman, E. M. Grant, and B. L. H. Sergeant have relinquished their commissions and have been granted the honorary rank of Captain.

War Substantive Captain M. S. Stevenson has relinquished her commission on account of disability and has been granted the honorary rank of Captain.

Lieutenants E. M. K. Irwin, N. M. Dwyer, M. T. Keyes, M. H. Swift, M. D. Cameron, J. H. Mitchell, A. M. McDonagh, and F. L. O'Rourke to be Captains.

COLONIAL MEDICAL SERVICE

The following appointments have been announced: J. Braun, M.D., Medical Officer, Gold Coast; J. Browne, M.B., Assistant Medical Superintendent, Mental Hospital, Singapore; J. K. Craig, M.B., Medical Officer, Kenya; C. H. Todd, M.B., Medical Officer, Seychelles; H. D. Crosswell, M.D., M.R.C.P., Medical Officer, Jamaica; T. Jezierski, M.D., Medical Officer, Fiji; T. K. Abbott, M.B., D.P.H., Senior Medical Officer, Seychelles; R. H. Heisch, M.B., Parasitologist, Kenya; W. M. Lewis, M.B., Medical Officer, Uganda; C. R. Philip, M.D., D.T.M.&H., Deputy Director of Medical Services (Supernumerary), Kenya.

Association Notices

SIR CHARLES HASTINGS CLINICAL PRIZE

The Sir Charles Hastings Clinical Prize, which consists of a certificate and a money award of 50 guineas, is again open for competition. The following are the regulations governing the award:

1. The prize is established by the Council of the British Medical Association for the promotion of systematic observation, research, and record in general practice: it includes a money award of the value of 50 guineas.
2. Any member of the Association who is engaged in general practice is eligible to compete for the prize.
3. The work submitted must include personal observations and experiences collected by the candidate in general practice, and a high order of excellence will be required. If no essay entered is of sufficient merit no award will be made. It is to be noted that candidates in their entries should confine their attention to their own observations in practice rather than to comments on previously published work on the subject, though reference to current literature should not be omitted when it bears directly on their results, their interpretations, and their conclusions.
4. Essays, or whatever form the candidate desires his work to take, must be sent to the British Medical Association House, Tavistock Square, London, W.C.1, not later than Dec. 31, 1948. The prize will be awarded at the Annual General Meeting of the Association to be held in 1949.
5. No study or essay that has been published in the medical press or elsewhere will be considered eligible for the prize, and a contribution offered in one year cannot be accepted in any subsequent year unless it includes evidence of further work. A prizewinner in any year is not eligible for a second award of the prize.
6. If any question arises in reference to the eligibility of the candidate or the admissibility of his or her essay the decision of the Council on any such point shall be final.
7. Each essay must be typewritten or printed, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address.
8. The writer of the essay to whom the prize is awarded may, on the initiative of the Science Committee, be requested to prepare

a paper on the subject for publication in the *British Medical Journal* or for presentation to the appropriate Section of the Annual Meeting of the Association.

9. Inquiries relative to the prize should be addressed to the Secretary.

KATHERINE BISHOP HARMAN PRIZE

The Council of the B.M.A. is prepared to consider an award of the Katherine Bishop Harman Prize of the value of £75 in 1949. The purpose of the prize, which was founded in 1926, is to encourage study and research directed to the diminution and avoidance of the risks to health and life that are apt to arise in pregnancy and child-bearing. It will be awarded for the best essay submitted in open competition, competitors being left free to select the work they wish to present, provided this falls within the scope of the prize. Any medical practitioner registered in the British Empire is eligible to compete.

Should the Council of the Association decide that no essay submitted is of sufficient merit, the prize will not be awarded in 1949, but will be offered again in the year next following this decision, and in this event the money value of the prize on the occasion in question will be such proportion of the accumulated income as the Council shall determine.

The decision of the Council will be final.

Each essay must be typewritten or printed in the English language, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address. Essays must be forwarded so as to reach the Secretary, to whom all inquiries should be addressed, at B.M.A. House, Tavistock Square, London, W.C.1, not later than Dec. 31, 1948.

MIDDLEMORE PRIZE

The Middlemore Prize consists of a cheque for £50 and an illuminated certificate, and was founded in 1880 by the late Richard Middlemore, F.R.C.S., of Birmingham, to be awarded for the best essay or work on any subject which the Council of the British Medical Association may from time to time select in any department of ophthalmic medicine or surgery. The Council is prepared to consider the award of the prize in the year 1949 to the author of the best essay on "The Value of Orthoptics in the Treatment of Squint." Essays submitted in competition must reach the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1, on or before Dec. 31, 1948. Each essay must be signed with a motto and accompanied by a sealed envelope marked on the outside with the motto and containing the name and address of the author. In the event of no essay being of sufficient merit the prize will not be awarded in 1949.

PRIZES FOR NURSES

The Council of the British Medical Association is prepared to consider the first award in 1948 of three prizes each of the value of 20 guineas for the best essay and three prizes each of the value of 10 guineas for the second best essay submitted in open competition by each of the following categories of nurses: (i) Pupil nurses; (ii) State-registered nurses working in a hospital; (iii) State-registered nurses not working in a hospital—i.e., district nurses, private nurses, etc.

The subjects of the essays for 1948 shall be: Category (i) "Suggested Improvements in the Methods of Training Nurses"; Category (ii) "Nursing the Patient, not the Disease: the Nurse-Patient Relationship"; Category (iii) "Difficulties of Nursing in the Patient's own Home and their Solution."

The purpose of these prizes is the promotion of systematic observation among nurses. In awarding the prizes due regard will be given to evidence of personal observation. No essay that has previously appeared in the medical press or elsewhere will be considered eligible for a prize. Nurses who are undergoing a course of training at a hospital are eligible to compete under category (i); nurses registered by the General Nursing Council are eligible to compete under categories (ii) and (iii). If any question arises in reference to the eligibility of a candidate or the admissibility of his or her essay, the decision of the Council of the British Medical Association shall be final. Should the Council decide that no essay submitted is of sufficient merit, no award shall be made. Each essay must be typewritten or legibly written, must be unsigned, and have enclosed in a sealed envelope containing the name and address of the candidate and the category into which he or she falls. Essays must be forwarded to reach the Secretary of the British Medical Association not later than May 31, 1948. Inquiries about the prizes should be addressed to the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1.

SCHOLARSHIPS IN AID OF SCIENTIFIC RESEARCH

The Council of the British Medical Association is prepared to receive applications for Research Scholarships as follows: Ernest Hart Memorial Scholarship of the value of £200 per annum; Walter Dixon Scholarship of the value of £200 per annum; four Research Scholarships each of the value of £150 per annum. These scholarships are given to candidates whom the Committee of the Association recommends as qualified to take research in any subject (including State medicine) to the causation, prevention, or treatment of disease. It will be given, other things being equal, to members of the medical profession.

Each scholarship is tenable for one year starting on Oct. 1. The scholar may be reappointed for not more than two additional terms. A scholar is not necessarily required to devote the whole of his or her time to the work of research but may hold an appointment at a university, medical school, or hospital, provided the duties of such an appointment do not interfere with his or her work as a scholar.

In addition, applications are invited for the first award of the Insole Scholarship of the value of £250 for research into the causation and cure of venereal disease.

Conditions of Award: Applications

Applications for scholarships must be made not later than February 30, 1948, on the prescribed form, a copy of which will be supplied on application to the Secretary of the Association, B.M.A. House, Tavistock Square, London, W.C.1. Applicants will be required to furnish the names of three referees who are competent to speak of their capacity for the research contemplated.

CHARLES HILL,
Secretary

GROUP OF VENEREOLOGISTS

Notice is hereby given of the formation by the Council of the Group of Venereologists, which shall be composed of members of the Association who are engaged predominantly in the practice of venereology. Members of the Association are invited to conform to this definition and are invited to complete the form set out below and return it to the Secretary, B.M.A. House, Tavistock Square, W.C.1, not later than April 19, 1948. The first general meeting of the Group will be held at a date to be subsequently announced in the *Supplement*.

CHARLES HILL,
Secretary

British Medical Association Group of Venereologists

Form of application for membership

To the Secretary,
British Medical Association,
B.M.A. House,
Tavistock Square,
W.C.1.

I wish to apply for membership of the Group of Venereologists which is composed of those members of the Association who are engaged predominantly in the practice of venereology.

I understand that the inclusion of any individual within the Group is at the discretion of the Group Committee subject to approval by the Council of the Association.

I am a member of the Association. I am a venereologist and am engaged predominantly in the practice of venereology.

Name (IN BLOCK CAPITALS).....

Qualifications..... Date of Qualifying.....

Experience in Venereology since Qualifying.....

Appointments

.....

Whether employed in full or part-time duties and, if first.....

of hours per week devoted to venereological work.

FOLIC ACID*

BY

JOHN F. WILKINSON, M.D., M.Sc., Ph.D., F.R.C.P., F.R.I.C.

Hon. Physician; Director of Department of Haematology,
Royal Infirmary and University of Manchester

olic acid," so named by Mitchell, Snell, and Williams (1, 1944) because of its isolation as a crystalline substance from spinach and other green leaves and grasses, recently identified constituent of the vitamin B group. It is necessary for the growth of two organisms—*Clostridium casei* E and *Streptococcus faecalis* (Str. lactis)—these have formed the basis of a microbiological method of estimation. It has been shown that a number of substances either similar to or identical with this particular "folie acid" (*L. casei* factor, as it is also termed) can be isolated from many other sources, such as yeast, liver, kidney, milk, mushrooms, grasses, and green leaves.

The isolation, identification, and, later, synthesis of folic acid was the culmination of a series of different independent investigations which became particularly active after Hill and Peterson (1940) demonstrated the existence of a vitamin-like substance essential for the growth of *L. casei*; several groups of workers (Mitchell *et al.*, 1941, 1944; Hestings *et al.*, 1941, 1944; Stokstad, 1943) have studied the growth factors for various bacteria and noted that extracts of plants or animal organs are essential for this growth. It soon became clear that there were several different but allied "folie acids," and of these at least four crystalline products have since been prepared and found to have different activities on the growths of *L. casei* and *S. faecalis*.

The very recent synthesis (Angier *et al.*, 1945, 1946) of one of these "folie acids"—pteroylglutamic acid—and the establishment of its identity with Stokstad's crystalline substance from liver (the liver *L. casei* factor) and with the essential growth factor for both *L. casei* and *Str. faecalis* have led to great advances in its therapeutic applications, especially since the pure substance has become generally available.

Vitamin B₁₂ and Folie Acid

Hogan and Parrott (1940), by feeding a diet containing the then known essential elements, produced a nutritional macrocytic anaemia in chicks which could be prevented or cured by a fuller's-earth concentrate from which yeast, green leaves, etc., containing a factor they named vitamin B₁₂ (Campbell *et al.*, 1944, 1945; Richardson *et al.*, 1942; O'Dell and Hogan, 1943). Vitamin B₁₂ was isolated from liver and yeast by Stokstad (1943) and Hestings *et al.* (1944), the yeast factor being less active in the liver factor for growth of *L. casei* and inactive for *S. faecalis*. Binkley *et al.* (1944) showed that vitamin B₁₂ from yeast was inactive for *L. casei* until after enzyme treatment, when it became equally active for *L. casei* and *S. faecalis* (Str. lactis R).

The vitamin-B₁₂-deficiency anaemia of chicks was made worse by the administration of sulphonamide derivatives—presumably through their bacteriostatic action preventing either synthesis of an essential anti-anaemic factor or digestion of the B₁₂ conjugate—much greater quantities of vitamin B₁₂ being required to relieve it. The effects of vitamin B₁₂ now appear to be identical with those of synthetic pteroylglutamic acid.

Pfiffner *et al.* (1943) isolated crystalline chick anti-anaemic factors from liver and yeast; the yeast factor was different from the liver vitamin B₁₂ in that the former did not promote growth of *L. casei* or *Str. faecalis* until it had been digested with enzymes. Thus the yeast factor for chick anaemia was considered to be a vitamin-B₁₂ conjugate which after digestion with a conjugase enzyme liberated the vitamin B₁₂ identical with the liver vitamin B₁₂.

Briggs *et al.* (1943, 1944) also suggested that the so-called liver vitamins B₁₀ and B₁₁ were responsible for the feather formation and growth, respectively, of chicks—the macrocytic anaemia and leucopenia being cured simultaneously—while Campbell, Brown, and Emmett (1944) produced with a synthetic diet a hypochromic anaemia and leucopenia in chicks which could also be prevented by crystalline vitamin B₁₂. Later work has shown that synthetic pteroylglutamic acid plus β -pyracin will prevent or cure this deficiency anaemia in chicks better than either separately (Scott *et al.*, 1945, 1946).

Folie Acid and Experimental Leucopenia in Rats

From an entirely different angle it was found that agranulocytosis or leucopenia, aplastic or hypoplastic anaemia, and thrombocytopenia with hypoplasia of the bone marrow could be produced quite readily in rats by the addition to their diets of 1–2% of sulphasuxidine (succinyl-sulphathiazole), sulphaguanidine, or thiourea (Martin, 1942; Daft *et al.*, 1943, 1945; Ransome and Elvehjem, 1943).

Complete haematological remissions were obtained by the use of liver extracts, folie acid concentrates (Axelrod *et al.*, 1943), or synthetic pteroylglutamic acid (Daft and Sebrell, 1943; Endicott, Daft, and Ott, 1945; Petering *et al.*, 1947). Totter and Day (1943) also noticed that xanthopterin relieved the leucopenia in rats fed sulphasuxidine on purified diets, but they and others have since failed to confirm this (Axelrod *et al.*, 1943; Daft and Sebrell, 1943; Wright and Welch, 1943).

Vitamin M and Folie Acid in Monkeys

Wills and her colleagues (1932, 1935), while studying tropical macrocytic anaemia, showed that a macrocytic hyperchromic anaemia with leucopenia and granulocytopenia

*Lectures (abridged) given to the Section of Experimental Medicine at the Royal Society of Medicine on May 13, 1947, and to the Medical Society of London on Feb. 9, 1948.

penia could be produced in rhesus monkeys fed on a diet similar to that normally taken by many Indians. The features of this condition in the monkey may resemble human tropical macrocytic anaemia or the sprue syndrome (Darby *et al.*, 1945, 1946a, 1946b), including a macrocytic anaemia, a megaloblastic marrow hyperplasia, leucopenia with granulocytopenia, diarrhoea, sore tongue and mouth, and diminution in resistance to infection. Both conditions responded to yeast preparations, such as "marmite," and certain less-purified liver preparations. The unknown factor concerned in relieving this nutritional cytopenia (termed "vitamin M" by Day *et al.*, 1936; Langston *et al.*, 1938) was shown to be different from the anti-pernicious-anaemia liver factor (Wills, Clutterbuck, and Evans, 1937).

Later the good results following the use of yeast, liver, and folic acid on the leucopenia in the macaca monkey were reported by Wilson *et al.* (1942, 1946) and by Waisman and Elvehjem (1943), while it was claimed by Totter *et al.* (1943, 1944) that xanthopterin would relieve the anaemia and leucopenia for a short time, giving a subnormal reticulocytosis (4.5%) but no other permanent improvement.

More recently Day *et al.* (1945) have tried a highly purified *L. casei* factor (active for *Str. faecalis* after enzyme digestion) with complete success in the vitamin-M-deficiency nutritional cytopenia in monkeys. Since synthetic pteroylglutamic acid relieved the condition completely, with a sharp reticulocytosis, rapid improvement in haemoglobin and in the red-cell and white-cell counts, and relief of symptoms, they suggested that vitamin M was probably a vitamin B₁₂ conjugate. Cooperman *et al.* (1945) noticed that fresh liver or lyophilized liver preparations were more active in the treatment of vitamin M deficiency in monkeys than ordinary dried liver powders, which lose some activity from the method of their preparation. They did not find any improvement in the monkeys when fed β -pyracin with folic acid, in contradistinction to their haematological effects in chick anaemia.

Folic Acid in the Treatment of Pernicious Anaemia

The synthesis of a "folic acid" (pteroylglutamic acid) was soon followed by the early reports of Vilter *et al.* (1945), of Moore *et al.* (1945), and of Spies *et al.* (1945) on its use in the treatment of sprue and pernicious anaemia. Receiving early supplies of this synthetic pteroylglutamic acid for trial, Wilkinson, Israëls, and Fletcher (1946) presented their preliminary results of the treatment of five patients with pernicious anaemia with folic acid when given orally and parenterally. We extended our investigations, and up to date have had some 25 cases of pernicious anaemia under continuous folic-acid therapy for periods up to one and three-quarter years—so that we are able to assess its later effects.

My first 20 patients all had the typical features of uncomplicated relapsing pernicious anaemia, and were chosen in conformity with the rigid criteria that I laid down some years ago and have often re-emphasized as being essential in testing the potencies of anti-pernicious-anaemia substances (Wilkinson, 1932)—namely, a patient with pernicious anaemia in relapse, with a megalocytic hyperchromic anaemia, megaloblastic marrow, achylia gastrica, no complications or marked cord involvement, and no effective anti-anaemic treatment to have been given previously.

A satisfactory response to treatment after the preliminary control period without treatment was judged by (1) a good reticulocyte response inversely proportional to the initial red-cell count within 5 to 10 days of beginning treatment; (2) transformation of the megaloblastic into a normoblastic marrow; (3) a sustained rise in red cells and haemoglobin

with a return to normal levels; and (4) clinical remission of symptoms. The patients were kept on an ordinary hospital diet without liver, other glandular products, eggs, while no medication was given apart from the "folic acid" under trial.

Pteroylglutamic acid was given (1) orally in the form of 5-mg. tablets as supplied by the manufacturer or (2) parenterally in aqueous solution, which was prepared by dissolving the pure folic acid powder in distilled water or in 0.9% saline with the addition of the minimal amount of disodium hydrogen phosphate or sodium bicarbonate and sterilizing by autoclaving at 10 lb. for 15 minutes or by passage through a Seitz filter. It is tasteless and offers no difficulty in administration, while intravenous or intramuscular injections do not cause any disturbances or ill effects at all. The patients were kept on pteroylglutamic acid only from the beginning, receiving no other therapy, with the exception of those developing subacute combined degeneration of the cord, who were later given liver or stomach extract.

Results of Parenteral Therapy

The patients referred to in Table I received folic acid either intravenously or intramuscularly in doses varying from 15 mg. daily to 200 mg. in a single dose.

*) Day since beginning treatment. [] Number of days on treatment

Case 1.—A married woman aged 63 had had intermittent treatment for pernicious anaemia since 1939. She was referred to my clinic in severe relapse—R.B.C., 1,260,000; Hb, 28%; C.I., 1.12; W.B.C., 4,200 (polymorphs 66.5%, lymphocytes 27%, large monocytes 4%, eosinophils 2.5%, basophils 0.5%); anisocytosis and poikilocytosis marked; nucleated red cells 0.5%; platelets scanty; pronounced megaloblastic marrow; achylia gastrica. After a preliminary control period (R.B.C., 850,000; Hb, 18%; C.I., 1.06; W.B.C., 4,300) she was given 15 mg. of synthetic pteroylglutamic acid intramuscularly daily for four doses, then a week later 15 mg. on alternate days for four doses.

With a prompt reticulocytosis (26% on seventh day), the sternal marrow became normoblastic, and on the 24th day she had R.B.C., 3,270,000; Hb, 72%; W.B.C., 7,200. After this the dose was gradually reduced from 10 mg. per day to 15 mg. on alternate days, on which she continued to 1.25 mg. daily in 1947, when she complained of paraesthesia in the fingers (R.B.C., 4,520,000; Hb, 94%); this increased with larger doses of pteroylglutamic acid, and on Oct. 7, 1947, of marked unsteadiness of gait, slight slurring of speech, and vibration sense in legs below knees, absent ankle jerks, loss of joint sense in the right foot; plantar reflexes brisk; flexor, knee-jerks brisk; Romberg's sign positive; power poor in limbs; there was no muscular wasting. R.B.C., 5,200,000; Hb, 106%; W.B.C., 5,200. The folic acid was continued and she was given parenteral liver extract weekly and "pepsac" 1 oz. (28 g.) daily, with gradual improvement in the neurological condition over the following months. On Jan. 6, 1948, there were still some para-

Case 2; male aged 58, treated with folic acid parenterally and then orally from 34th day. Preliminary control period omitted from chart. Note change of time scale at 34th day.

and feet; ankle-jerks were negative, Romberg's sign ve, vibration sense was absent in both legs, plantar reflexor; R.B.C. 5,320,000, Hb 104%.

A joiner aged 58 had had pernicious anaemia for 18 which he had taken treatment very irregularly. He had been referred to me with R.B.C., 1,210,000; C.I., 1.16; W.B.C., 2,900 (polymorphs 49%, lymphomonocytes 5%, eosinophils 1%; reticulocytes, 1%; xanthoblastic marrow hyperplasia; achylia gastrica. He 75 mg. of pteroylglutamic acid intravenously on five days, the blood rising steadily from R.B.C., Hb, 22%; reticulocytes, 1.2% (first day), with cytosis of 45.6% (seventh day), to R.B.C. 5,220,000 96% on Aug. 23, 1946. (See Fig. 1.) On the 1st the marrow showed a cellular normoblastic hyperplasia was continued with 15 mg. intramuscularly 5 days, and then 20 mg. orally daily. (See Table I and on Aug. 23 the dose was gradually reduced to 5 mg. daily, and the blood count, which had remained fairly March 4, 1947, began to fall slowly until on April 30 : R.B.C., 3,880,000; Hb, 92%; C.I., 1.05; W.B.C., leucocytes, 2.8%. Treatment was then increased to 10 mg. daily, with a good improvement, so that on May 7 his : R.B.C., 4,610,000; Hb, 94%; C.I., 1.02; reticulocytes, 2.8%; platelets, 141,000; M.C.V. 84 c.u., M.C.H.C. 39%. He remained about this level, in good 10 mg. of pteroylglutamic acid daily, and on Jan. 14, red R.B.C., 4,130,000; Hb, 88%; C.I., 1.06; W.B.C.,

Results of Oral Therapy

Table II are the main details of 17 patients with pernicious anaemia who were treated with pteroylglutamic acid in daily doses of 20 mg. initially, with reductions to 10 mg. daily as the blood counts returned normal. The following are illustrative cases.

A married woman aged 50 was admitted to hospital with features of pernicious anaemia, R.B.C., 950,000; C.I., 1.26; W.B.C., 4,400, very active megaloblastic marrow, and achylia gastrica. She was treated with 10 mg. of synthetic pteroylglutamic acid orally daily, and rapidly with reticulocytosis (32.6%) and reversion to normal normoblastic hyperplasia of marrow on the ninth day. C. 1,560,000 and Hb 36% on 11th day. (See Fig. 2.) The dose was reduced to 10 mg.; the blood count R.B.C. 3,570,000, Hb 78% (31st day), and then daily dose of 5 mg. to R.B.C. 3,110,000, Hb 74%. Pteroylglutamic acid was increased, and ultimately was daily before the count could be raised to R.B.C. 4,130,000, Hb 94% on Jan. 27, 1948. She was well clinically.

Case 9.—A male garment-maker aged 47 collapsed at work and was admitted to hospital under my care with pernicious anaemia (R.B.C., 1,470,000; Hb, 36%; very active megaloblastic marrow hyperplasia; achylia gastrica). He was given 20 mg. of pteroylglutamic acid per day orally, and responded very well clinically, with reticulocytosis (34.6% on the eighth day) and an active normoblastic marrow (tenth day); on the 23rd day he had R.B.C. 3,720,000 and Hb 88%. (See Table II.) His treatment was reduced gradually to 5 mg. twice weekly, producing on Sept. 16, 1946, R.B.C., 5,610,000; Hb, 106%; C.I., 0.94; W.B.C., 6,200. Thereafter he gradually fell to R.B.C., 3,800,000; Hb, 98%; C.I., 1.2 on May 6, 1947, and the treatment was increased to 15 mg. daily with improvement in the blood count which has remained at Jan. 12, 1948 (now on 10 mg. daily), R.B.C., 5,370,000; Hb, 100%. Clinically he is very well indeed.

Immediate Results of Treatment

From the results summarized in Tables I and II the following points may be noted:

Rapid haemalogical responses followed the intravenous or intramuscular administration of pteroylglutamic acid from 15 mg., intramuscularly, to 200 mg. in a single dose, as has been observed with liver extracts when given by the same routes. A daily dosage of 20 mg., orally, was quite adequate to initiate good reticulocytosis and clinical remission in most cases, although the reticulocyte peaks were rather lower than would have been obtained with an active liver or stomach preparation. There was not a striking difference between the rates and the heights of the reticulocyte responses whether the oral or the parenteral route of administration was employed; nor was there more than a very slightly greater rate of red blood cell and haemoglobin formation after parenteral pteroylglutamic acid.

FIG. 2.—Case 5; female aged 50. Preliminary control period omitted from chart.
Note change of scale from 25th day.

Not all the patients showed full reticuloeytosis in keeping with the initial red cell counts: thus, Case 11 gave only 9.8% (expected 18-26%) on the 7th day, with initial red cell count of 1,540,000; Case 13, 8.9% (expected 14-19%) on the 9th day, with red cell count of 2,000,000; and Case 15, 9% (expected 10-18%) on the 8th day, with initial red cell count of 2,150,000. Though subsequently there were satisfactory clinical and hematological improvements.

With the rise of the haemoglobin and red cell counts to normal limits it was often possible to reduce the doses of pteroylglutamic acid to 2.5-5 mg. daily for a time. Eventually, however, with most of the patients the daily maintenance dose had to be increased to 10-20 mg. again after varying periods of time on these smaller doses, since the red cell count and haemoglobin percentage tended to fall slowly—e.g., Cases 5, 6, 8, 9, and 10. (See Fig. 2.)

Macrocytosis still persisted in many patients even when the hemoglobin and red cell count were within normal limits. The white blood cells and platelets showed the expected improvement usually seen after liver or stomach therapy, but not more than 50% of the normal.

In all three cases the original megaloblastic sternal bone marrow was rapidly converted to normoblastic ones, and this was complete before the maximal reticulocyte

peaks were reached. This result is in keeping with the findings of Levy (1947) and others, who did serial stem biopsies after giving a single oral dose of 50 mg. of pteroylglutamic acid to one case, and resembles the effects of live virus under similar conditions.

The *clinical symptoms* in this group showed rapid improvement in most cases, very much in the same way and at the same speed as noted after standard liver extracts or stomach therapy (Wilkinson, 1931a, 1931b). Occasionally, —e.g., Cases 12, 15, and 17—however, showed slower response to pteroylglutamic acid in these doses. The patient begins to feel better even before the maximum reticulocyte count is reached, and this is followed by a rapid improvement in general symptoms; flatulent dyspepsia and diarrhoea, soreness of the tongue disappears, and there is a very marked improvement in the dyspnoea, palpitation, and lack of appetite returns, and the whole outlook of the patient becomes more cheerful and normal. Splenomegaly, if normally as with ordinary standard treatment, but, as well expected, the achylia gastrica persists. On the other hand, have not seen any improvement in the peripheral neuropathies, paraesthesiae, or the more marked symptoms or signs of cord involvement (see below).

Summarizing, the *immediate* effects of treatment with quate doses of synthetic pteroylglutamic acid, whether administered orally or parenterally, to severe cases of per-

anaemia were good, the result being almost but quite as effective as a potent liver extract or preparation of hog's stomach. On the 7th day, a good increase in red blood cells, haemoglobin percentage, and reticulocytes, and cessation of the megablastic to normoblastic marrow, the macrocytosis failed to persist; complete relief of all the clinical symptoms and signs of pernicious anaemia was noted except those associated with the central nervous system.

Later Results of Pteroylglutamic Acid Therapy

Of greater importance are the later effects of continuous pteroylglutamic acid therapy. So far, after nearly 3 years, I have the following additional observations to make: (See Tables I and II.)

No ill effects or reactions due to pteroylglutamic acid have followed its continued oral or parenteral use in dosages ranging from 2.5 to 200 mg. Total dosages in some cases have reached 10 g. Many of my patients have remained on doses varying between 2.5 mg. weekly and 20 mg. daily, however, with some it has often been necessary to increase dosages owing to a very definite tendency for the red cells and haemoglobin percentage to fall again in the subsequent months; in some cases this may probably be due to too small a maintenance dose, which is ordinarily between 5 and 10 mg. daily. A few patients have been slow in regaining normal cell counts and haemoglobin percentages. Although the cell counts and haemoglobin percentages were within the normal

macrocytosis still tended to persist in many patients, in corpuscular volume, mean corpuscular haemoglobin ration, and haematocrit percentage often being outside normal range. (See Table III.)

TABLE III

x	R.B.C.	Hb %	Haematocrit % (M 40-54; F 37-47)	M.C.V. c.μ (82-92)	M.C.H.C. % (32-36)

Other observers have reported the marked beneficial effect of pteroylglutamic acid on pernicious anaemia and Wright, 1946; Davidson and Girdwood, 1946; Meyer *et al.*, 1946; Goldsmith, 1946; Harrison and 1946; Vilter *et al.*, 1947; Wilkinson, Israëls, and 1946; but Kaufmann and Schwager (1946), (1947), and Vilter *et al.* (1947) do not think that pteroylglutamic acid is as good as a potent liver extract in patients, and over the longer periods of observation I inclined to agree, for we have long known that both extracts and hog's stomach do produce and maintain remissions in pernicious anaemia with an entire return to the normal clinical and haematological state (Mason, 1931a, 1931b).

Acute Combined Degeneration of the Spinal Cord and Peripheral Neuritis

Perhaps the most important considerations in pteroylglutamic acid therapy are those concerning the neurological effects, and the results are disquieting. Eight of my 20 patients had signs and symptoms of central nervous system involvement: one (Case 10) had the symptoms before the beginning of pteroylglutamic acid treatment, which did not bring about any improvement in them; three (Cases 1, 17, and 18) showed definite deterioration in their neurological condition; while four (Cases 4, 8, 15, and 16), originally free of any neurological involvement, developed within two weeks acute symptoms and signs of subacute combined degeneration of the cord after receiving pteroylglutamic acid therapy—with peripheral polyneuritis, loss of vibration in the lower legs, extensor plantar responses, and poor knee-jerks and ankle-jerks in both legs; nevertheless haematological conditions improved considerably. None of these patients showed any improvement on only increased doses of pteroylglutamic acid, but some improvement is to be observed since the institution of internal liver extracts or desiccated hog's stomach orally (Mason, 1933).

There is a most important point to bear in mind when using "folic acid" preparations, since the development of changes is difficult to reverse by any form of therapy, one of the prime points in the treatment of pernicious anaemia is to give sufficient potent anti-anaemic therapy to prevent the development or progression of neurological symptoms.

These observations parallel those of Spies and Stone (1941) and Vilter *et al.* (1947), who found that during the pteroylglutamic acid treatment of 21 patients with pernicious anaemia four developed neurological signs, while of the seven got worse on folic acid. Further, Heinle and 1947 observed, as I have, an acute onset of subacute combined degeneration of the cord in one patient with

pernicious anaemia under treatment with pteroylglutamic acid (making a total of three out of their 27 cases). Similar cases are reported by Ross, Belding, and Paegel (1948), Bethell *et al.* (1946), Hall *et al.* (1946, 1947), Davidson and Girdwood (1947), and Heinle *et al.* (1947), who also noted the failure of pteroylglutamic acid to relieve or prevent neurological changes. On the other hand, Doan (1946) and Goldsmith (1946) claimed that the neurological symptoms were relieved by pteroylglutamic acid.

In view of the general experience it is very clear that patients with pernicious anaemia must still have full treatment with potent liver extracts or hog's stomach whether pteroylglutamic acid is given or not. The latter may have a place in initial therapy where quick results are needed, for those sensitive to liver extracts, and perhaps for ill-nourished patients, although highly potent liver extracts are quite adequate. I am fully of the opinion that pteroylglutamic acid is neither the best nor the cheapest form of treatment for pernicious anaemia and must not be given alone to patients with neurological symptoms.

Refractory Macrocytic Anaemias

From time to time cases of macrocytic anaemia are seen with blood pictures resembling pernicious anaemia but usually having normoblastic marrows, although refractory megaloblastic anaemias are also seen. They may have normal gastric acidities or achlorhydria gastrica, and are refractory to ordinary anti-anaemic treatment. Some are said to respond to treatment with proteolysed liver extracts, while others certainly do not.

Four such refractory cases were treated in my clinic with pteroylglutamic acid (three orally, one intravenously) without the slightest haematological or clinical improvement. They all had normoblastic marrows, two had achlorhydria, one a normal gastric acidity, and one hyperacidity. (See Table IV.) None of these patients had any obvious or

All four patients had normoblastic marrows.

detectable nutritional deficiencies and were on perfectly adequate dietary intakes. They do not correspond to the nutritional macrocytic anaemias so commonly quoted in the American literature by Spies and others, in which there were marked nutritional deficiencies.

Davidson and Girdwood (1946, 1947) have noted some response in liver-refractory anaemias, but the blood remained macrocytic until further liver therapy was given, while Watson *et al.* (1945) did not observe any improvement in similar refractory cases after 5 mg. of a folic acid concentrate daily for six days.

Achrestic Anaemia

This is a primary hyperchromic megalocytic anaemia characterized by a megaloblastic hyperplasia of the marrow (identical with that of pernicious anaemia), free hydrochloric acid in the gastric secretion, little or no disturbance of the gastro-intestinal tract, no neurological symptoms or signs, no pyrexia, and no evidence of haemolysis—the

general anatomy resembles pernicious anaemia, and there is a failure in varying degree to respond to specific anti-pernicious-anaemia therapy, the course being sometimes prolonged with the help of blood transfusions (Wilkinson and Israëls, 1935, 1936).

The following is the report of a patient with achrestic anaemia under the care of Dr. Stock.

A housewife aged 26 complained of weakness, lack of energy, dyspnoea, palpitation, and increasing pallor. There were no gastro-intestinal symptoms, glossitis, or involvement of the central nervous system or peripheral nerves. No haemolysis was to be found. Gastric secretion contained normal amounts of hydrochloric acid. Sternal puncture on May 7, 1947, showed an active cellular marrow with 42.5% megaloblasts, while a few days later it contained 8% megaloblasts and 34% normoblasts and was still very active and cellular. A blood count on April 21 showed: R.B.C., 900,000; Hb, 25%; W.B.C., 5,000; reticulocytes, 1.6%; M.C.V., 128 c μ ; M.C.H.C., 31.3%. On April 30 it was: R.B.C., 1,200,000; Hb, 23%; W.B.C., 3,800; platelets, 93,600. She was given synthetic pteroylglutamic acid, 20 mg. per day orally, and a reticulocyte peak of 27.4% was obtained on the 8th day. The bone marrow still showed 8% megaloblasts on the 10th day, and on May 9 the R.B.C. was 1,800,000; Hb, 45%; platelets, 206,000; and reticulocytes, 15.2%. The haematological and clinical conditions continued to improve, and on June 4 her blood count was R.B.C., 3,600,000; Hb, 75%; C.I., 1.04; W.B.C., 10,000. At this stage she was given liver extract instead of folic acid, and on Dec. 17 reached R.B.C., 4,500,000; Hb, 95%; C.I., 1.05; W.B.C., 8,600.

(The conclusion of these lectures, with a list of references, will appear in our next issue.)

ACUTE INTUSSUSCEPTION IN CHILDHOOD

BY

BRENDA MORRISON, M.D.

AND

DONALD COURT, M.D., M.R.C.P.

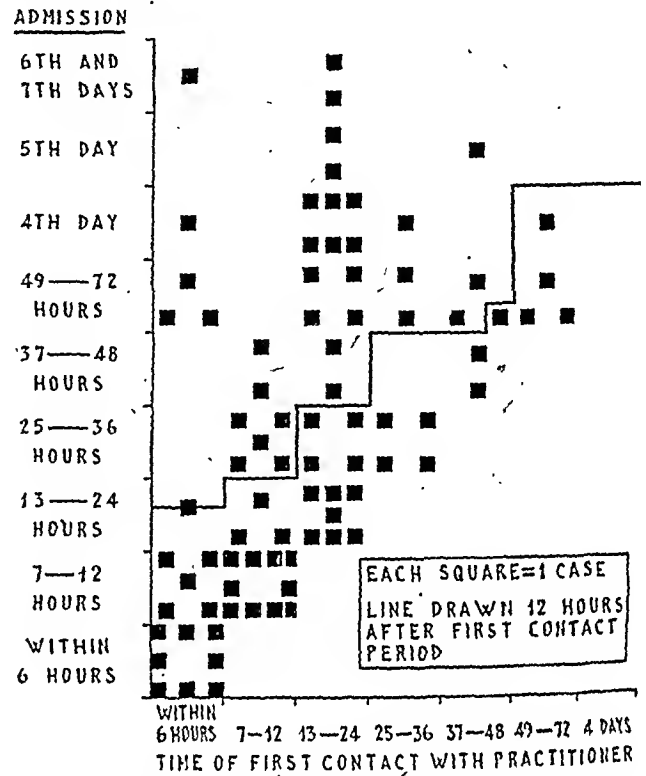

From the Department of Child Health,
Royal Victoria Infirmary, Newcastle-upon-Tyne

The detailed study of 100 children treated for acute intussusception in this department from 1944 to 1946 has revealed certain facts which we believe will help the family doctor as well as those responsible for treatment. In the past thirty years the reported mortality has fallen from nearly 40% to less than 10%, yet while the figure for children treated in the first 24 hours is below 5% it rises steeply to 20% or more when the disease remains untreated for more than two days.

Time is an important and often a vital element in all disease, and we have paid special attention to the exact duration of the illness and the times when the different symptoms and signs made their appearance, when the doctor was called, and when the child reached hospital.

Of the 100 cases there were 83 in which accurate time-intervals were known, and of these 66 (80%) were seen by the doctor within the first 24 hours, but only 34 (41%) were admitted to hospital within that period. (See Graph.) Of the 82 seen within 48 hours only 53 had reached hospital by the end of the second day, while the admission of the remainder was not completed until the seventh day. This delay is culpable in view of the increasing mortality after the second day. It suggests that the problem of acute intussusception, in this area at least, is primarily not concerned with improving methods of treatment, but rather with the ability to suspect this disease in the first 24 hours and ensure prompt admission to hospital.

The accepted description in British textbooks is so dramatic that the failure of the family doctor to recognize it in many cases is unexpected. Further, even the passage of blood from the bowel does not invariably bring the disease to mind; for of those who passed blood and were seen by the doctor 41 (79%) were admitted within 12 hours and 11 (21%) were not admitted within 12 hours of the event. Of the latter, 6 were not admitted for 48 hours or over. This

Graph showing the relation between contact with the family doctor and admission to hospital in 83 cases.

failure to recognize acute intussusception in its early stages suggests that the traditional description may need modification in the light of local experience.

When faced with a child who may have intussusception the first and most important step is to take a detailed history of the illness from the mother or from someone who has been with the child all the time. This is so essential for diagnosis in an early case, and so valuable in assessing the need for resuscitation and operation in many of the later cases, that we have always considered it worth while to send for the mother if she was not with the child even though many of our patients live up to 50 miles from the hospital.

At the beginning the physical signs alone may not be sufficient to indicate the need for admission to hospital. The diagnosis should not be delayed until the discovery of an abdominal tumour, as its detection may require a level of experience which comes only from frequent and regular contact with the disease in a large hospital.

The description of the disease is similar in most British textbooks. A healthy, well-nourished male child, with no history of recent illness, at 9 months or shortly after weaning is seized by violent abdominal pain, with pallor and collapse. The pain recurs at intervals of about half an hour and the spasms last from a few seconds to a few minutes, the child drawing its knees up and rolling about. Vomiting may occur, although it is not a prominent symptom. Apart from an initial stool, constipation is the rule, though after a variable unspecified interval dark-red blood resembling red-currant jelly is passed per rectum, and the diarrhoea then becomes apparent.

Such a picture is obviously diagnostic of acute intussusception, but during the first 24 hours it was present in only 39 of the 100 cases; yet if we aim at a mortality rate below 5% such treatment must be completed within the first two days. We shall therefore reconsider in detail the early clinical picture of this disease.

Aetiological Factors

Age.—The accepted age of onset is 6 months. Table I shows that, though the condition is rare before 6 weeks, 33 cases occurred between 3 and 6 months. In fact, almost as many

TABLE I.—The Age in 100 Cases of Acute Intussusception

Age:	Months				Years		
	Under 3	3-5	6-8	9-11	1-2	2-6	7-12
No. ..	3	33	35	11	8	7	3

occurred in this period as in the following three months. There were 82 in the first year, and after 18 months the disease was uncommon.

Sex.—A striking male predominance is generally accepted, but in this series 45% were females.

Nutrition.—The view that well-nourished, often exceptionally well nourished, children are mostly affected was confirmed. In 34 children whose state of nutrition was recorded it was described as "very good" in 80 and "poor" in only 4.

Precipitating Factors.—Dietary changes or indiscretions can be excluded with reasonable certainty in many cases, especially those under 4 months. After this age the extent of intermittent unofficial additions to the diet is unknown. As the actual process of weaning or the recent establishment of mixed feeding was present in only 29 cases they cannot be considered of major significance.

Respiratory or Other Infective Illness.—In 10 children the intussusception followed a few days' malaise, usually with evidence of mild respiratory infection, and in four there was a preceding gastro-intestinal infection. This is not the place to discuss the possible role of infection in aetiology, but these cases are important because the infective signs may be considered sufficient to account for the illness, and the intussusception may be missed or the diagnosis delayed. In one such case the child had bronchitis for several days and later became ill. Vomiting, pain, and even the passage of blood from the rectum went unnoticed, and he was admitted to hospital moribund from bronchopneumonia. A very tight ileo-ileal intussusception was found and reduced at operation, but the child died.

The Clinical Picture in the First 24 Hours

TABLE II.—The Main Combination of Symptoms in the First 24 Hours

Clinical Features	No. and % of Cases
Pain, vomiting, and blood	39
Pain and vomiting	34
Vomiting, blood, and minimal pain	10
Vomiting	5
Pain and blood	4
Pain	4
Blood	4

In 82 cases the health and behaviour in the preceding week had been completely normal and the onset of the disease was sudden and unexpected. Almost always the parents were able to give the exact time when the initial vomit, screaming attack, or collapse occurred. In the remaining 18 the precise time of onset was blurred by a few days of respiratory, gastro-intestinal or other infection, though even here careful inquiry revealed a sharp change in the symptoms consistent with the beginning of the bowel invagination. Pain in one or more of its varied expressions was the presenting symptom in 55 of the children; vomiting in 34; and collapse, with the child found pale and cold in the cot or pram, in five. The spontaneous passage of obvious blood from the bowel was the first indication of the disease in only four cases. The remaining two cases started with a stubborn refusal to feed.

Pain.—The recognition of pain in babies is often difficult. Some scream, some cry loudly, others whimper, and an important minority are quietly restless. It is in the last type of case that diagnosis may be long delayed. We have seen a child drawing his knees up and blanching with spasms of pain, rolling his head about, and then rolling over on to his face, yet never uttering a sound. The spasmodic nature of the pain is a constant feature. Distress is often severe during the spasms, and in over half the cases there was also striking pallor. Between the spasms the child lies quietly, as though exhausted, and often sleeps. They last from a few seconds to a few minutes, and the interval between them may be anything from five minutes to several hours, but as the condition worsens they tend to become more frequent. During the attacks of pain the child draws the knees up to the abdomen, and the older babies and children roll over on to their hands and knees and sometimes around the bed.

Vomiting.—Vomiting occurred in 88% of the children in the first 24 hours. It is usually an early and often the presenting symptom. At first whatever is in the stomach is vomited during or after a spasm of pain, and the amount is not large unless the baby is drinking well between attacks. The vomiting, however, can be very forceful, and there may be slight bile-staining, making the vomitus yellow or light green. When obstruction is established the vomit changes in character: it is now copious and dark green or brown, resembling coffee-grounds, or is frankly faecal. It is very important to distinguish between these two types of vomiting, as the latter indicates serious intestinal obstruction.

The Bowels.—The frequency and character of the stools are together particularly important, because the common alternative diagnosis leading to delayed admission is infective gastro-enteritis. The traditional picture is of one or two normal or loose stools at the onset, followed by the passage of blood and mucus without faeces. In the week before the disease started 96 children had normal stools and four a mild diarrhoea. After the onset only eight had complete constipation, and they were all admitted on the first day. The passage of apparently normal stools was more common than we expected: in 36 this occurred in the first 24 hours and in eight as late as the second or third day. Unless early treatment has taken place abnormal stools are eventually passed in most cases. The main types of stool in 80 children with detailed information on this point were as follows: blood or blood and mucus, 46%; blood intimately mixed with faeces, 21%; a stool streaked with blood, 19%; frequent small brown liquid stools, 5%; loose, green, and undigested stools, 7%. Mucus was present in 30% of the children with abnormal stools. In 93% the total number of stools before admission was three or less, and only in the small group with six or seven offensive brown liquid stools could the dangerous alternative diagnosis of infective gastro-enteritis by the family doctor be justified.

Spontaneous Passage of Blood.—This is considered the cardinal diagnostic feature of acute intussusception, and stress is laid on its appearance within the first six hours or, less commonly, towards the end of the first day. Its relation to the duration of the disease in the present group is shown in Table III.

TABLE III.—Time when Blood was First Passed

At the onset of symptoms	4	On the third day	2
Within the first 12 hours	30	Not recorded	..
Within the second 12 hours	22	Never	24
From 24 to 48 hours	16		100

It was completely absent in 24 cases, 13 of which were admitted to hospital on or after the third day. In only 56 cases was blood passed during the first 24 hours. It is such a disturbing event for the parents that it is unlikely to be disregarded, and so in a disease where progress must be measured in hours rather than days the fact that it may be a late or an absent sign is of great diagnostic importance. In fact, if the present mortality is to be lowered the condition must be suspected on other evidence alone.

Physical Signs.—The physical examination can be conclusive, but during the vital first day of the illness it may yield very little evidence. Although obvious constitutional disturbance was present after admission in 80 cases, the proportion of babies who do not seem to be particularly ill between the spasms must

be higher when first seen by the family doctor. The positive signs fall into two groups—those of "shock" or constitutional disturbance, and the local changes in the abdomen. The factors concerned with the production of "shock" or collapse are probably nervous "reflex" effects from the pulling on the mesentery by the intussusception, and from the severe colicky pain and loss of fluid in vomiting. They develop together and it is difficult to differentiate between them, though the former is probably the more important, particularly during the first 24 hours. Marked pallor, quietness, and limpness, with a rapid heart rate, are frequent, and can be quickly produced by a severe spasm of pain followed by vomiting. On the first day these often alternate with crying and restlessness due to pain. Sunken eyes, loss of skin tone, and dryness of the mouth denote dehydration and become more evident on the second and third days. When intestinal obstruction is established the combination produces a desperate picture. The baby with anxious, grey, cyanotic facies, restless movements of head and limbs, and coldness and blueness of the extremities then enters the final stage of complete peripheral circulatory failure.

Fever.—Here we wish to make a substantial alteration in the traditional picture. It is often stated that the temperature in intussusception is normal or subnormal. Others, while admitting the possibility of moderate fever, say that this is a late or terminal sign. In our cases some rise in temperature was the rule, even in the first day of the disease, and in one-half of them it was as high as 100–104° F. (37.8–40° C.). Fever therefore cannot be adduced as evidence in favour of infective gastro-enteritis. What is more, in two children seen since this survey was completed a temperature of 104° F., with no evidence of systemic infection, was associated with frank convulsions in the first 48 hours of the intussusception.

Signs in the Abdomen.—In a vigorous child the abdomen can be very difficult to palpate because of the strength of the muscles and the resistance induced by tenderness. Once obstruction is established the distension may make it difficult to feel a mass. On the other hand, in a collapsed baby the tumour may be felt and handled with the greatest of ease and little or no protest. It must be emphasized that ease of palpation arises presently from ease to ease, and if the history is suggestive admission should never be delayed until the tumour has been felt. It is often helpful to examine the abdomen with the baby in the prone position, on his hands and knees, or on the mother's lap. The mass, as is well described in most accounts of the disease, is cylindrical or sausage-shaped and lies somewhere in the line of the colon, except in ileo-ileal invaginations. The consistency varies from time to time; the tumour can often be felt to harden under the hand during palpation, while at other times it may become so ill-defined that it is difficult to be sure of its existence. Localized tenderness over the tumour is usually present and there may be well-marked muscle-guarding. This is a sign of some importance, especially if the mass is not very well defined.

The lower border of the liver and the edge of the rectus muscle may, however, deceive even the most experienced. Local masses are less confusing, as they are usually multiple and are present in the rectum as well as the colon. When the mass is at one of the colonic flexures and under the costal margins it may be quite impalpable. Though a tumour was felt in 88% of this series the difficulties have been stressed in order to emphasize the danger of waiting for its detection before sending the child to hospital. Distension and visible peristalsis are grave signs, as they denote an established obstruction. They indicate a very serious condition and the need for careful pre-operative preparation.

Rectal Examination.—Rectal examination can give information in three main ways and should never be omitted:—(1) the presence of blood on the finger or its passage after the examination, (2) the direct palpation of the apex of a low intussusception, and (3) the empty, even ballooned, condition of the rectum in many cases but requires experience for its interpretation. Distension, or an emptiness in the right iliac fossa, is not a reliable sign, as it is quickly masked by the movement of the child and the rectum.

Rectal Irrigation Experiments.—We feel that there are scarcely any contraindications to the use of rectal irrigation. A single experiment is sufficient, if need be, repeated examination

will provide the answer in almost every case. Where circumstantial evidence is strong but conclusive proof is lacking, a laparotomy under modern hospital conditions adds little to the risk while leading to accurate diagnosis and prompt treatment. Though the experience of diagnostic barium enemas in this department is small it is sufficient for us to disagree with those who say that the manipulation involved has no adverse effect on the child's general condition. The proper use for this technique is in the investigation of suspected sub-acute or chronic intussusception.

The Anatomical Type of Intussusception

It is well known that mortality is higher in intussusception involving the small bowel. From the clinical point of view it is sufficient to divide the different anatomical types into three main groups: (1) small bowel, including ileo-ileal and ileo-ileocolic; (2) boundary, with ileocolic, ileocaecal, and caecocolic types; and (3) large bowel, arising at some distance from the ileocaecal valve. The relative distribution and associated mortality in the present series is shown in Table IV. Although the number of cases

TABLE IV.—Anatomical Type

	Small Bowel	Boundary	Large Bowel	Unknown
No. of cases ..	14 (14%)	77 (77%)	4 (4%)	5 (5%)
Deaths ..	2 (14%)	8 (10%)	—	—

the small-bowel group here does not admit of statistic proof there is no doubt of their greater risk. It would be valuable if a clear clinical distinction could be made so that the small-bowel invaginations could be discovered very early in the disease. Unfortunately this cannot always be done with certainty, but the following tentative conclusion can be drawn from the present survey.

Small-bowel Intussusception.—(1) Ileo-ileal:—A study of the literature suggests that these invaginations occur more commonly after 2 years of age. This was true of our three cases. The spontaneous passage of blood is a late event. An abdominal tumour is difficult to feel and may be situated at or just below the umbilicus. Because of these two features, and in spite of the early collapse which is often present, admission is delayed, and the children are seriously ill when they reach hospital. (2) Ileo-ileocolic:—There were 11 of this type with a clinical picture very similar to ileo-ileal intussusception, though the ultimate passage of the intussuscepiens through the ileocaecal valve leads to more frequent recognition of the abdominal tumour.

Boundary Intussusceptions (ileocolic, ileocaecal, and caecocolic types).—In these 77 children blood was passed early in the disease in most cases. An abdominal tumour was readily felt, especially in the ileocaecal and caecocolic varieties, where it may be in the left flank when the child is first seen. In nearly one-third of this group the head of the intussusception was felt on rectal examination. Ileocolic invaginations occupy a position midway between the ileo-ileal and the ileocaecal and large bowel types. They have no special features which permit their accurate separation from the rest of the boundary group.

Large Bowel (colocolic intussusception).—There were few invaginations of this type, starting at some distance from the ileocaecal valve. The clinical picture was similar to the boundary intussusceptions, and there were no deaths.

Treatment

Acute intussusception is a serious emergency, and when so many different medical functions are involved—diagnosis, resuscitation, anaesthesia, operative surgery, and general paediatric care—there will be divided authority and responsibility. It is therefore essential for treatment to be in the hands of a team each member of which knows his part and the extent of his responsibility.

We find that the best working arrangement is to have the paediatrician responsible for the conduct of the case

with a special concern for resuscitation at all stages of the illness, full consultation with the surgeon taking place on diagnosis, the best time to operate, and the treatment of complications.

Pre-operative Treatment

The important part played by shock and later by dehydration in the outcome of the disease demands their prompt control. Further, if this resuscitation is to be fully effective it must be well under way before the operation begins. We cannot help feeling that in previous accounts of the disease some of the deaths which occurred during or soon after the operation and were attributed to surgical intervention were in fact deaths from uncorrected circulatory failure. The operation was rather the last straw for a circulation already in a state of serious breakdown. Further, the technical difficulty of canalizing a vein in a small child on the operation table, with the surgeon and his assistant working against time to get the gut replaced and the wound closed, and the small space available, are likely to defeat the most experienced, and such a situation should never be allowed to arise. It is equally risky to leave the transfusion till the end of the operation, when the child may be irreversibly collapsed and the technical difficulties greatly increased by the peripheral circulatory failure and the empty veins.

During the early part of this series it became our practice to transfuse any child showing evidence of collapse or dehydration or of established obstruction. Serum or plasma was given initially—approximately 100 ml. for an infant below 9 months and 150 ml. for those between 9 and 18 months. The aim was to get the child as fit as possible before going to the theatre—even though this meant a delay of several hours. Saline solutions were given later if required. The results were encouraging, and the practice was extended to include all babies under 18 months and older children with more than 24 hours' history or with signs of collapse. Unexpected difficulties in reduction necessitating much manipulation or even resection have been encountered at operation when the local and general signs have not given cause for alarm, and in such cases the advantages of an established pre-operative infusion have been great. In the ordinary course of events, after a successful reduction the drip can be discontinued 12 to 24 hours after operation, but when there has been much vomiting or any abdominal distension it may be necessary to continue it for several days combined with gastric suction.

Operation

Both anaesthesia and the technique of surgical reduction are the province of the specialist and we are not competent to offer detailed comment. We know from experience, however, how important are the quality of anaesthesia, both during and after the operation, and the necessity for obtaining the help of a skilled anaesthetist. If this is done and the induction is started only when the surgeon and his assistants are quite ready the length of anaesthesia is reduced to a minimum. These babies tend to vomit during operation, and a nasal catheter passed into the stomach beforehand and left in position will often assist the anaesthetist and later the paediatrician. Although speed and gentleness are obviously desirable in all cases we find that there is considerably less trouble from vomiting and distension when reduction is carried out inside the abdomen.

Immediate Post-operative Care

Sudden deterioration, with the production or progression of circulatory collapse, is common in the immediate post-operative period and requires continuous supervision—in the theatre, on the way back to the ward, and in the ward—by someone experienced in resuscitation and able to take the decisive action required. Prompt clearing of the airway

oxygen, and the prevention of vomiting and inhalation by gastric suction may all be necessary. A small stomach-tube should be passed at the end of the operation if this has been unwisely omitted earlier. Circulatory failure or excessive haemorrhage calls for the immediate administration of plasma or whole blood.

Later Measures

In a straightforward case we have continued with intravenous saline for 6 to 12 hours after operation as a slow drip, meanwhile re-establishing fluid administration by mouth as described below. Where vomiting of dark-green fluid or faecal fluid occurs, hourly gastric suction and full replacement therapy by the parenteral route are employed until only clear fluid or nothing at all is obtained from the stomach for some hours. If 20–30 ml. of water is given orally after each aspiration an idea of the amount of absorption taking place can be obtained, and infection and soreness of the mouth and oesophagus are minimized.

In most cases fluid is given as sips of water as soon as the child has recovered consciousness, and 1 oz. (28 ml.) hourly is started within 5 to 6 hours after operation. This is increased to 2–4 oz. (57–114 ml.) two-hourly, according to the size of the baby, if no vomiting occurs, and milk feeds at two-hourly intervals can be started after 12 hours. If the child is breast-fed the mother is admitted and feeding started about 12 hours after the operation.

After 48 hours, if the bowels have been opened—with the help of a glycerin suppository if necessary—and feeds are being taken and retained, there is no need for continued stay in hospital, and early discharge is the rule. In most cases some degree of fever continues for several days, but it tends to subside steadily, and in our experience need not prevent the child from going home. The wound can be sealed off with "elastoplast" over a gauze dressing, and normally needs no further attention until the stitches are removed on the seventh or eighth day, which can readily be done at an out-patient visit. It is more satisfactory to have the child return to the hospital for a general examination and inspection of the wound than to have the dressing done at home, though the latter may be necessary if the home is too far away or travelling is difficult. The length of stay in hospital in uncomplicated cases is three days. Children with ileostomy or anastomosis, of course, require a longer period in hospital and special surgical care suitable to the nature of the operation.

Severe post-operative vomiting of obstructive type may be encountered, and is presumably due to a temporary ileus from oedema or haemorrhage into the bowel wall. Hourly gastric suction and adequate parenteral fluids may have to be continued for some days, but are usually effective. This is not the place to discuss the detailed measures required to maintain water-and-salt balance in such cases.

Use of Enemata, Alone or Combined with Surgery

Here we enter the difficult but important field of comparison. A careful study of the many accounts of acute intussusception written in the past 50 years reveals the disturbing fact that many of these are so lacking in precise information about age, the duration of the disease at the beginning of treatment, the length, character, and effect of pre-operative resuscitation, and the quality of anaesthetic and surgical skill employed that comparison is difficult and unprofitable. Further accurate recording of the time relationships in this disease is indispensable if we are to achieve a valid assessment in strictly comparable groups of cases.

Table V sets out our results in Newcastle-upon-Tyne beside a similar series treated by primary surgery in America. Table VI shows the results obtained by Hipsley (1937) in Australia, Nordentoft (1943) in Denmark, and

Nyborg (1943) in Sweden, using reduction by enemata alone or combined with surgery. The excellent results obtained by Hipsley and Nyborg with the lowest recorded death rate in this disease would at first sight suggest that the combined approach is superior to primary surgical reduction. This is an important practical point, implying the need for the initial use of barium enemata in all early cases and the availability, whenever necessary, of staff expert in this technique.

A most careful reading of the three papers, however, suggests that the real factor responsible for the excellent results is less the therapeutic method employed than the

the age of the child, the anatomical type of invagination; and the degree of difficulty encountered in the surgical reduction.

Summary and Conclusions

A detailed study is made of 100 cases of acute intussusception in children treated at Newcastle-upon-Tyne.

It is concluded that the mortality from acute intussusception can be substantially reduced only by its diagnosis and treatment within the first 24 hours.

The clinical features of this series of cases suggest that the traditional picture of the disease may require modification in the following details:

1. A considerable number of cases occur between 3 and 6 months of age.
2. Male predominance is not always present.
3. Spontaneous passage of blood from the bowel is often a late sign in terms of the period available for effective treatment.
4. In acute cases a sudden illness, occurring in a previously healthy child between 3 and 18 months old, characterized by recurrent abdominal pain and vomiting, especially when associated with pallor or collapse, should be regarded as intussusception and sent to hospital without delay.
5. The emphasis in diagnosis should be placed on the total history rather than on any individual physical signs. Though an abdominal tumour was felt in a high proportion of the cases in this series, the family doctor, seeing relatively few cases, should not wait for its detection. Rectal examination should never be omitted, as blood may be found in this way before its spontaneous escape from the bowel. The presence of fever is quite consistent with acute intussusception and should not lead to the delaying diagnosis of infective enteritis.
6. The outlook is mainly determined by the duration of the disease before treatment and the efficiency of pre-operative resuscitation. In expert hands, primary surgical reduction and hydrostatic pressure supplemented by surgery are both effective. There are certainly no grounds for a change from the

TABLE VII.—Detailed Analysis of Deaths in the Newcastle Series

Case No.	Age	Duration of Disease	Type of Intussusception	Pre-operative Plasma	Time of Death after Operation	Probable Cause of Death
550*	7 mths.	4 days	Ileocolic	None	4 hours	Circulatory failure; cyst of vitello-intestinal duct removed at operation. No resuscitation.
562*	4 mths.	4 days	Ileocaecal	150 ml.	14 hours	Prolonged intestinal obstruction; extensive fatty change in liver; toxic changes in heart and kidneys
1239*	8 mths.	5 days	Ileocolic	Less than 100 ml.	15 hours	Prolonged intestinal obstruction; degenerative and fatty changes in heart, liver, and kidneys; pulmonary haemorrhage
1334†	8 mths.	3 hours	Caecocolic	150 ml.	30 hours	Lipoid pneumonia—aspiration. Death not directly due to intussusception
2467†	2 years	72 hours	Ileo-ileal	100 ml.	24 hours	Circulatory failure; possible recurrence of intussusception
2335*	4 mths.	49 hours	Caecocolic	40 ml.	36 hours	Recurrent circulatory collapse; necrosis of caecal mucosa, pulmonary collapse
2456†	4 mths.	67 hours	Ileocolic	200 ml.	9 hours	Operation postponed for 24 hours; barium enema given; continued intestinal obstruction and circulatory collapse
3033*	7 mths.	5 days	..	240 ml. (100 ml. saline)	12 hours	Prolonged intestinal obstruction
3435*	3 mths.	33 hours	Ileo-ileocolic	200 ml.	48 hours	Progressive circulatory failure; inadequate response to pre-operative resuscitation; gangrene of gut—peritonitis
4147*	3½ mths.	45 hours	Ileocolic	170 ml.	5 hours	Progressive intestinal obstruction with relentless increase in distention

* Difficult reduction. † Easy reduction.

high proportion of cases coming for treatment early in the disease. Nearly 90% of Nyborg's children had been dealt with in the first two days. In the larger group collected by Nordentoft this was not the case, and the combined results are less satisfactory than in cases treated by surgery alone. Although Hipsley does not give precise details of the duration in each case, the average in each of his three groups was 16, 17, and 24 hours, suggesting again that the majority of his cases were treated early in the disease. What is more, 84% of his deaths occurred in children who had had the disease from two to five days before treatment was carried out.

Table VII gives the main details of the ten Newcastle children who died. The factors which in our experience determine the outcome of this disease are the duration before treatment, the efficiency of pre-operative resuscitation,

surgical technique which has long been accepted in this country, though more expert supervision at all stages of the disease and operation by interested as well as experienced surgeons are desirable.

We are grateful to Professor J. C. Spence for his unfailing encouragement; to Drs. Swinburne, Walton, Whitehouse, and late Dr. Sheriff for the very high standard of their case reports which alone made this study possible; and, lastly, to Dr. Whiteham for his help with the figures.

AN UNUSUAL CASE OF ADRENAL CARCINOMA

WITH A NOTE ON THE APPLICATION OF A NEW
COLOUR TEST

BY

L. R. BROSTER, D.M., M.Ch., F.R.C.S.

AND

JOCELYN PATTERSON, M.Sc., Ph.D., F.R.S.Ed.

(From Charing Cross Hospital)

This case is recorded not only because it was unique in our series in having general clinical appearances of a typical Group I virilism associated with an adreno-cortical tumour instead of marked bilateral hyperplasia, but also because the later stages were accompanied by manifestations of disturbances in both carbohydrate and steroid metabolism of a particularly striking order. Moreover, the case afforded an opportunity of applying the urinary colour test recently devised by Patterson (1947) for distinguishing between adreno-cortical tumour and marked adrenal hyperplasia.

Case Report

The patient, a girl aged 14½ years, was kindly referred by Dr. H. B. Hayman, of Gloucester. He wrote: "She had been admitted to the City General Hospital, Gloucester, on April 20, 1947, with a four-months history of fits followed by coma. During the past 18 months she had become very hairy, the voice had deepened, her secondary sex characters had not appeared, and she had never menstruated. On admission she was semi-comatose, with a marked right-sided hemiplegia and all the signs of an upper-motor-neurone lesion. The latter completely disappeared within the next three days. She then developed epileptiform fits accompanied by incontinence of urine. Each fit lasted 30 minutes, with a return to normal. The fits then began to increase in frequency, with lengthening periods of unconsciousness.

"On examination her complexion was dark and the nipples pigmented. She was drowsy and her voice was deep. There was marked hirsuties, also a male pubic triangle. The clitoris was enlarged to the size of the tip of the little finger. The blood pressure was 120/85 and the cardiovascular system was normal. The central nervous system showed on the right side a seventh-nerve palsy, a dilated pupil, and an extensor plantar reflex. The eyes deviated to the left, with papilloedema more pronounced on the right side than on the left. A large tumour was present in the left hypochondrium. The cerebrospinal fluid and urine were normal, the blood urea was 25 mg. per 100 ml., and the sugar-tolerance test revealed marked hypoglycaemia, with blood-sugar figures following 50 g. of glucose ranging from 55 mg. per 100 ml. at 15 minutes to 70 mg. at 120 minutes, and the urine showing a trace of sugar."

On July 7, 1947, the patient was admitted into Charing Cross Hospital. She had that gnomish appearance typical of marked Group I virilism, with the figure of a boy rather than a girl. The chest was flat, the musculature well developed, with limbs short in proportion to the torso. During lucid periods the mentality appeared dull but psychologically feminine. The blood urea was 19 mg. and fasting blood sugar 35 mg. per 100 ml., haemoglobin 104%, and the 17-ketosteroid excretion 1,980 mg. a day—about 2½ times the highest level we have seen reported. The dehydroisoandrosterone test (Patterson: see Addendum) was strongly positive. X-ray examination showed calcified streaks in a large adrenal shadow, a normal pituitary fossa, and premature epiphyseal fusion corresponding to the age of 20 or over. From the day of admission till July 20, when she died, there was a succession of fits, with stupor and recovery. The stupor would last as long as a whole day. At times she was irritable and incontinent, and on waking would cat voraciously. On July 13 she was roused temporarily by 2 minims (0.12 ml.) of adrenaline intravenously, and on the 14th from a deep stupor by 5 ml. of 50% glucose intravenously. On July 16 she was seen

by Dr. Gardiner-Hill, who suggested that the hypoglycaemia was due to the unopposed action of insulin—the adrenal medulla being destroyed—and that she be put on a high-protein low-carbohydrate diet to avoid the further stimulation of insulin production. During the attack in which the blood sugar was estimated the value fell to 15 mg. per 100 ml. (Hagedorn and Jensen method). There was no return of any central nervous symptoms, except that during July 19 and 20 the pupils began to dilate with the head turned to the right, and the temperature began to rise.

At necropsy the left adrenal tumour together with attached kidney weighed 6 lb. 8 oz. (2.98 kg.). The thyroid gland was enlarged, the pituitary was normal, and there was no evidence of any secondary deposits.

Report on the Tumour

The following are the findings of Prof. Willis, of the Royal College of Surgeons, with regard to the adrenal cortical tumour.

"*Gross Description.*—The left adrenal tumour is rounded, well circumscribed, measures 22 cm. in main diameter, and weighs nearly 6 lb. (2.72 kg.); it consists of almost fluid degenerated and haemorrhagic material, with only a thin rim of living tumour tissue in places. The kidney and also the other pieces of organs submitted (liver, spleen, thyroid, right adrenal, uterus and ovaries, and pancreas) show no obvious abnormalities, except for marked post-mortem changes.

"*Microscopical Description.*—The adrenal tumour consists of large, rounded, and irregular cells of variable size, irregularly arranged in masses and trabeculae and showing extensive areas of degeneration. The structure is that of a malignant adrenal cortical tumour, although mitotic figures are not numerous. Spleen, adrenal, kidney, pancreas, liver, ovary, and thyroid show pronounced congestion and post-mortem changes (especially in the pancreas and kidney) and scattered large bacilli which are probably post-mortem invaders. Other noteworthy points are: kidney shows patchy areas of calcification in both the cortex and medulla; post-mortem changes in pancreas are so advanced that islet tissue cannot be distinguished; ovary contained abundance of healthy primary and vesicular follicles; and thyroid shows a mild degree of colloid retention."

Discussion

Clinically the patient did not show such an advanced degree of virilism as other cases of similar age group in our series where the underlying pathology was due to pronounced adrenal hyperplasia. Nevertheless, the 17-ketosteroid excretion was 20 to 50 times that commonly found in the latter group. This finding makes the case a notable example of gross discrepancy between clinical manifestations of virilism and the 17-ketosteroid excretion.

It is also a matter of interest that the opposite adrenal was present. This seems to conform to the rule that in heterosexual virilism both adrenals are invariably present, whereas in isosexual precocity the carcinoma may arise in a solitary adrenal. We have experienced the latter combination on three occasions: two boys, one with a tumour imbedded under the right lobe of the liver and one with a huge tumour of the left adrenal; and a girl, also with a huge tumour on the left side, with an androgen excretion of 260 mg. a day, who was being treated concurrently with the present case. These patients are of the fat, ruddy-complexioned type, more akin to Cushing's syndrome.

Some of the difficulty of correlating clinical manifestations with 17-ketosteroid output undoubtedly arises from differences in the type of androgen secreted. Crooke (1946) puts forward the view that the association of adreno-genital tumours with virilism in some instances and with basophilism in others might be accounted for on the theory that the androgenic steroids of the first type are derived from incompletely elaborated hormones, whereas in the second type they derive from vital hormones, and that it

Clinical examination revealed gynecomastia in all, varying in degree from "as in a girl" to "female" and appearance. Holl's second case had great tenderness to palpation. The breasts are described as being nodular or "lumpy" to palpation. Holl and Lissner recorded secretions from nipples. Pigmentation of the areola and Montgomery's follicles are also mentioned. In four of

Up to the doctors and dentists, pharmacists welcomed the new National Health Service Act, said Mrs. J. K. Irvine, president of the Pharmaceutical Society of Great Britain, speaking in Edinburgh on April 2. Subject to satisfactory terms of service and remuneration they were prepared to take their part in the new service. Under the Act pharmacy became a complete public service applying to the whole population. The new service was going to change pharmacy not only as the medical benefit part of the Act of 1911, but also as the pharmacy of that day. Pharmacy under the Act bore a put an end to the dispensing doctor, most of the old practice will be done by pharmacists. It meant a complete reorganisation of prescribing and dispensing. Pharmacists were taking the Act on trust, because as yet they had not seen the terms of service or the remuneration. They would not be paid for the time was now short for the Government to make arrangements with the Minister of

uses the penis and testes were small, and testicular atrophy in some instances was extreme—the "size of a pea" (Bittorf). Two authors reported the genitalia as "normal," two others made no mention of their state. A varicocele occurred in two cases on the same side as the adrenal tumour. Secondary sex characters seemed to show little changes, and most cases had a normal masculine hirsuties, although in two instances the beard area was described as becoming softer. In a 15-year-old boy there was no facial hair, and the pubic hair was described as transverse female type. In Bittorf's case the voice was high-pitched, but there had been no recent change. Holl, who recorded acne and dilatation of skin veins in one of his cases, was the only author to describe changes in the skin.

The general nutrition and body weight were normal in four of the cases, Holl's second case was grossly obese, and Simpson and Joll's (1938) case gained weight before becoming emaciated. Two cases had lost weight. Facies described in only three of the cases—two as being "soft" (one patient changed so greatly that his acquaintances failed to recognize him), and the third (our case) as normal. There was a loss of libido and potency in three cases; the patients seem to have become sexually indifferent. The development of homosexuality is not recorded. A palpable abdominal mass or "fullness" was present in all cases, and in all but one was left-sided. Two cases showed increased pigmentation of the skin, in two it was absent, and in the remainder it was not commented upon. Blood pressure was normal where it was recorded.

Pyelography was carried out in four cases, and in each there was depression downwards of the kidney, and in some there was rotation. Two radiologists observed a mass above the kidney. The single glucose-tolerance curve in the series revealed an impaired tolerance to glucose. No basal metabolic rate estimations have been recorded. X-ray examination of the skull and sella turcica, when made, was normal.

Estimations of oestrogens and androgens were recorded in three cases: all showed moderate excess of androgens, and in the two cases investigated gross excesses of urinary oestrogens were found, as follows:

Simpson and Joll.—Androgens: comb-growth capon units, 5-100 per litre (normal, 8-25). Oestrogens: 100-6,400 M.U. per litre (normal, 20). Aschheim-Zondek test negative.

Roholm and Teilum.—Androgens: 54-164 C.C.U. (normal, <25). Oestrogens: 750-8,000 M.U. (normal, <20). Gonadophin: 30-50 R.U. (normal, <30).

Armstrong and Simpson.—Ketosteroids: May, 1942, 34 mg.; November, 1942, 108 mg. (normal 6-23 mg. in 24 hours).

Treatment.—In two of the four cases operated upon nothing could be done (Armstrong and Simpson; Holl, case 1). In Simpson and Joll's case the tumour was removed, but the patient died from secondary deposits. Joll's second patient was operated on successfully by Jertle, and 12 months later was still alive and well, showing no evidence of secondary deposits.

Course.—In five cases the condition ran its course in a few months, the patients dying of cachexia and secondary deposits. In Simpson and Joll's case the duration was three years and in Roholm and Teilum's case five years. Holl's case remains unique as a possible cure. The younger patients have all died quickly; the older group survived longer.

Post-operative Results.—Holl's patient regained his masculine appearance; his penis and testes became larger; libido and potency returned. The breasts, which had become very tender and congested, rapidly became painless and soft, pigmentation disappeared, and when last seen they were still getting smaller. Simpson and Joll's patient gained weight, the breasts became smaller, the genitalia larger, and there was a partial return of libido and potency.

This was only temporary, and he redeveloped all his symptoms owing to secondary deposits.

Pathology.—All cases have been due to malignant adrenal tumour arising in the adrenal itself, except in Lissers case, which arose from an adrenal rest. All metastasized except Holl's second case. Metastases have occurred in lungs, bones, liver, lymph nodes, and the opposite adrenal.

Case Report

The patient, a policeman aged 40, was admitted to hospital in February, 1942, complaining of pain below the left costal margin, night sweats, and loss of weight. Examination revealed a tender mass closely resembling a spleen protruding two finger-breadths below the left costal margin. The patient was of good physique and showed no signs of loss of weight. Whilst in hospital he ran a low-grade intermittent pyrexia. Splenomegaly was suspected, but full investigation revealed no clear cause for the pyrexia or the "splenomegaly." He was discharged home and told to report to the out-patient department in two months. When seen again in May, 1942, he complained of a pain in the right breast, and was found to have developed bilateral gynaecomastia. On his readmission to hospital it was observed that the pain in the left side of the abdomen had worsened and now radiated to the left hip. He was then investigated as a possible case of adrenal neoplasm.

On examination the patient was of normal bodily contour, with no obesity or feminine distribution of fat. The facies and hair distribution were normal for an adult and had shown no recent change. To external examination the genitalia also appeared normal. There was no abnormal pigmentation. A well-marked bilateral mammary swelling could be felt, due to the presence of nodular glandular tissue. Clinical examination of the cardiovascular and respiratory systems revealed nothing of note; the blood pressure was 128/88. The central nervous system was normal, and urinalysis showed nothing abnormal. Haematological investigation revealed a slight hypochromic anaemia. The leucocyte count varied between 7,500 and 12,300 per c.mm., and there was a slight absolute lymphocytosis. The Wassermann reaction was negative.

Routine chest radiography showed a "possible calcified primary complex, but no evidence of recent disease." The report on the intravenous pyelogram read: "Right pyelogram normal; left kidney seems to be displaced downwards and laterally. ? due to mass"; and the retrograde pyelogram: "No abnormality of pelvis or calices of left kidney, but the kidney is displaced downwards and laterally. Right side, nil."

17-ketosteroid investigations gave the following 24-hour results: May 22, 34 mg.; Sept. 30, 108 mg.

At laparotomy on June 17 Mr. T. A. Hindmarsh found a large adherent and necrotic tumour above the left kidney. Because of the vascularity of the tumour mass, its size, and extensive adhesions, no attempt was made to remove it. Subsequently the patient deteriorated rapidly; he became emaciated and jaundiced, he developed ascites, and his liver became enlarged and nodular. Death occurred during November, 1942, some eleven months from the onset of his symptoms. There was a terminal haematuria.

Abstract of Dr. J. G. Thomson's Necropsy Report

The body is of a well-developed but poorly nourished subject; there is deep jaundice. The breasts are larger than normal in a male and measure 7.5 by 8 cm., with a maximum thickness at nipple level of 1 cm. The nipples are prominent, free from hairs, and measure 0.7 cm. in diameter. Hair on the trunk shows the normal masculine distribution.

Internal Examination.—Lying above the left kidney, which is compressed and distorted but nowhere invaded, is a large lobulated tumour measuring 17 by 13 by 19 cm. It appears to be well encapsulated, and section reveals that the tumour mass is divided into lobules 3.5 cm. in diameter by fibrous septa. Approximately three-quarters of the growth is haemorrhagic or yellow and necrotic; the remainder is pink in colour and soft in consistency. No left adrenal is recognizable.

Secondary deposits are present in both lungs; they are mainly small, and measure up to 2.5 cm. in diameter (the left lung

has six secondary deposits, the right has eight). The liver is enormously enlarged to 8,010 g. by secondary deposits up to 7 cm. in diameter, most of which show extensive yellow foci of necrosis. An isolated secondary deposit is present in the twelfth thoracic body, and the first and second lumbar bodies are diffusely infiltrated by tumour. The breasts are readily separated from the surrounding tissues, and the left, without nipple, weighs 28 g.; section shows it to consist of firm fibrous tissue. The prostate is normal in size and appearance. The testes are not significantly reduced in size; they measure 4 by 2.5 by 2 cm. (with epididymis) and together weigh 28 g. The cut surfaces are brownish and atrophic.

The following organs show no obvious abnormalities: thyroid, pituitary, right adrenal, spleen (240 g.), brain (1,310 g.), heart (208 g.), and right kidney.

Histology.—This confirms the adrenal origin and carcinomatous nature of the tumour. Differentiation varies a great deal and nuclear irregularities are frequent, but even in the secondary deposits resemblances to adrenal cortical cells in nucleus and the lipid content of the cytoplasm are retained to a varying degree. Necrosis is everywhere a prominent feature, and in the sections studied half the tumour is necrotic. Whilst a fair degree of resemblance to adrenal cortical cells is present the picture nowhere approximates to that of the adrenal cortex or of a well-differentiated cortical adenoma, and in particular the normal relationship of cortical cells to sinusoids is nowhere evident. *Testes* show early atrophic changes with marked fibrous thickening of the walls of the tubules, diminution of the cellular content, and an increase of wear-and-tear pigment in the interstitial cells. *Breasts* show dilated ducts containing protein material and cells, and abundant glandular tissue, producing a picture not unlike that of a female breast.

Comment

Acquired feminism due to carcinoma of the adrenal cortex causes a well-defined syndrome of gynecomastia, abdominal tumour, atrophy of the external genitalia, and loss of libido and potency. The condition is rapidly fatal, especially in the younger patients. Biochemically there are a moderate excess of urinary androgens and a gross excess of oestrogens. A most striking feature is the invariable presence of a palpable abdominal tumour.

The possibility that feminism might be due to hyperplasia of the adrenal cortex has been suggested by Broster and Vines (1933), who have clearly shown that virilism can be due to hyperplasia of the adrenal cortex as well as to carcinoma or adenoma. They consider that, similarly, feminism may be due to hyperplasia of the adrenal cortex. Roholm and Tellum (1942) also discuss this possibility.

In our clinic we are investigating cases of hypogonadism, with or without gynecomastia, and are considering hyperplasia of the adrenals as a possible aetiological agent.

Summary

The condition of feminism is defined and discussed.

The eight reported cases due to carcinoma of the adrenal cortex are analysed in detail.

A clinical report and necropsy findings of a case of feminism due to carcinoma of the left adrenal are described.

Our thanks are due to Dr. J. G. Thomson, of the Department of Pathology, for the report on the necropsy and the histological findings, to Dr. Freda K. Herbert for the 17-ketosteroid investigation, and to Dr. S. Whately Davidson for the radiological reports.

IDIOSYNCRASY TO *d*-TUBOCURARINI CHLORIDE

BY

T. CECIL GRAY, M.D., D.A.

AND

JOHN HALTON, M.B., Ch.B., D.A.

(From the Department of Anaesthesia, Liverpool University)

Since first introducing pure *d*-tubocurarine chloride as an aid to anaesthesia it has been clear to us that patients show a marked variability in their reactions to average clinical doses of this substance. The following factors are known to influence the individual response.

Age.—As with most drugs, the administration of *d*-tubocurarine chloride must be made with caution in the extremes of age. Children up to the age of puberty tolerate the drug well provided that a dose-for-weight ratio (2 mg. per stone (6.35 kg. body weight) is used. The aged, on the other hand, show varying susceptibility, and some patients past the allotted span have required as much *d*-tubocurarine chloride as their less brethren in the prime of life.

Body Weight.—In so far as it bears a relation to muscle mass—e.g., in children—this is a useful guide to dosage, but in adults a maximum initial dose of 15 mg. should not be exceeded. It is, however, a general rule for the muscular well-developed patient to tolerate *d*-tubocurarine chloride well.

Physical Condition.—The dosage must be modified considerably in cachectic and feeble patients.

Drug Tolerance.—There is clinical evidence to show that patients who show a natural or acquired tolerance to the opium and barbiturates tend to require a larger dose of *d*-tubocurarine chloride than normal.

Some authorities would modify the dose in the presence of certain anaesthetic agents, either in particular. In our opinion it is preferable to reduce the amount of the toxic anaesthetic agent.

These, then, are the salient factors upon which the initial dosage of this drug is computed, but they do not account for all the variations. Minor variations in reaction on either side of normal are often seen, and the following two cases demonstrate very clearly that this variability may be of serious degree and consequence.

Case 1

The patient, a man aged 40, was admitted to hospital with an obstructive lesion of his main bronchus. He was losing weight and had a cough with repeated haemoptysis. Five days before the present examination a bronchoscopy had been performed under local analgesia, but it was decided to repeat the examination and carry out a biopsy. The following sequence of events took place.

1 p.m.—Anaesthesia was induced with *d*-tubocurarine chloride, 15 mg., and thiopentone, 0.5 g., and respiratory arrest ensued. The lungs were inflated with oxygen, and bronchoscopy was performed. On bronchoscopy the picture was that of an inoperable carcinoma of the bronchus. Owing to the non-return of respiration the surgeon was asked not to take a biopsy. The examination was speedy and at no time was the patient deeply cyanosed, oxygen being insufflated through a side tube of the bronchoscope and artificial respiration performed whenever he went a little "off colour." At the end of the examination there was no sign of any respiratory arrest; the patient appeared to be more than usually relaxed and comfortable. An airway was introduced, a facepiece applied, and artificial respiration maintained by manual compression of the rubbering bag of a closed-circuit anaesthetic machine.

After 30 Minutes.—"Prostigmin," 5 mg., and atropine, 1 mg. (1.3 mg.), were given intravenously. No effect was observed. The patient continued in apnoea.

After 60 Minutes.—The dose of prostigmin and atropine was repeated. Following this a little diaphragmatic respiration became evident. Within ten minutes, however, these slight respiratory efforts had ceased.

After 105 Minutes.—A further dose of prostigmin and atropine was administered with a very similar response, the respiration being temporarily stimulated but fading off after ten minutes.

After 165 Minutes.—The dose of prostigmin and atropine was repeated, and this time the slight diaphragmatic response was maintained. The general condition of the patient had remained excellent throughout, and the pulse and blood pressure were normal.

After 180 Minutes.—The patient was in good condition and was showing evidence of continued diaphragmatic respiration.

After 195 Minutes.—Blood-stained fluid was regurgitated from the stomach and some entered the air passages. Bronchoscopy was carried out without delay and as much fluid as possible was aspirated from the bronchial tree. The patient's blood pressure was 150/75 and his pulse rate 90 a minute, but from this time his condition began to deteriorate and for the first time cyanosis became a feature of the case, tending to increase despite vigorous artificial respiration with oxygen.

After 270 Minutes.—The pulse was of poor volume and the blood pressure had fallen. Ephedrine, 1½ gr. (0.1 g.), was administered intravenously and slight improvement followed. The respiratory function was now practically in abeyance.

After 285 Minutes.—Nikethamide, 4 ml., was given intravenously, with a resultant transient improvement in the general condition. But circulatory failure was supervening.

After 300 Minutes.—The cyanosis had increased and the patient was now grey. Nikethamide, 4 ml., was repeated.

After 311 Minutes.—The pulse was imperceptible, and despite all efforts the patient died at 6.14 p.m., 314 minutes after the induction of anaesthesia.

Necropsy.—A very extensive carcinoma of the left main bronchus was found, and this rendered the whole of the left lung practically functionless. The right lung showed evidence of the aspiration of a large amount of blood-stained fluid which had undoubtedly reduced the aerating surface of this sole remaining lung below the minimum required for sustaining life. The stomach and intestines showed numerous small and recent punctate haemorrhages. These were not evident in the duodenum or in the large bowel. It was the blood from these which had been regurgitated from the stomach. Nothing else was found. There was no evidence of a persistent or enlarged thymus.

Remarks

This most severe case of hypersensitivity to *d*-tubocurarine chloride might not have been fatal had the possibility of regurgitation been anticipated and suitable precautions taken on the institution of artificial respiration. Before this accident the patient was apparently recovering and a fair degree of diaphragmatic respiration had returned. The necropsy was performed within three hours of death, and the haemorrhages of the gastro-intestinal tract were clearly of recent origin. The condition of the intestines bore a close resemblance to that discussed by Cole (1946) in his experiments performed on dogs to find a lethal dose of *d*-tubocurarine chloride. There was no suspicion or evidence of any myasthenic element in this case.

In view of this misfortune it was decided to give all patients a trial dose, namely, one-third of that estimated as necessary for the induction. That this was a wise precaution is amply confirmed by the sequence of events in Case 2.

Case 2

A woman aged 40 was found to be suffering from pulmonary tuberculosis in May, 1943. At no time had she complained of any symptom or shown any sign of myasthenia gravis, but she stated before operation that she had always reacted badly to drugs, especially to analgesics and opiates. Apart from the tuberculous disease of the right lung her condition was good and her blood picture normal. She was presented for a first-

stage thoracoplasty on the right side. After premedication with morphine, 1/6 gr. (11 mg.), and atropine, 1/150 gr. (0.43 mg.), one hour previously, *d*-tubocurarine chloride, 6 mg., was administered.

After 1 Minute.—The patient had become completely curarized and all respiration had ceased. A pharyngeal airway was introduced and the facepiece of a closed-circuit anaesthetic machine applied. The lungs were inflated with oxygen.

After 2 Minutes.—Thiopentone, 0.3 g., was injected and the patient was placed in the thoracoplasty position. The operation was started and the anaesthesia was maintained with a 50% mixture of oxygen and nitrous oxide.

After 45 Minutes.—Her respiratory efforts returned and the diaphragmatic contractions gradually increased in amplitude. The anaesthesia was perfectly satisfactory throughout the procedure, but there was more than the usual amount of haemorrhage.

After 130 Minutes.—The operation was completed. The respiratory excursion was now much improved, but it was still inadequate. Prostigmin, 5 mg., and atropine, 1/50 gr. (1.3 mg.), were administered intravenously. This produced an immediate effect. All the reflexes were present when the patient left the table and she was fully conscious and co-operative ten minutes after arriving in the ward.

Further Progress.—The patient developed some basal consolidation accompanied by rusty sputum, but this cleared quickly and her convalescence was otherwise uneventful. On inquiry she stated that after the injection of *d*-tubocurarine chloride she felt "like a fish out of water"—as if she could not breathe. She could just remember the beginning of the injection of thiopentone.

Four weeks later she was presented for her second stage. The premedication was as before, and it was decided to follow the same regime as on the previous occasion in order to confirm the hypersensitivity. A test dose of 5 mg. of *d*-tubocurarine chloride was administered. The following sequence of events took place.

After 1 Minute.—There was complete ptosis of the eyelids and she was quite unable to raise them.

After 1 Minute 5 Seconds.—Her respirations were gasping and her pulse rate 130 a minute. She was showing signs of distress, and 0.3 g. of thiopentone was injected, the facepiece applied, and artificial respiration begun.

After 3 Minutes.—The facepiece was now accurately in position and the administration of a mixture of nitrous oxide and oxygen (25%) was started.

After 5 Minutes.—Manual full inflation of the lungs was met by a slight resistance at the end of the "stroke."

After 9½ Minutes.—There was some diaphragmatic flutter with slight arm movements; 0.2 g. of thiopentone was administered.

After 14 Minutes.—The respirations were regular but the tidal volume was small. The pulse rate was 80 a minute.

After 25 Minutes.—The respirations were still regular but small in volume and tending to be grunting. Pulse rate, 80 a minute.

After 43 Minutes.—The operation was terminating. Prostigmin, 3.5 mg., and atropine, 1/50 gr. (1.3 mg.), were administered. An immediate effect was observed.

After 45 Minutes.—The patient was coughing and groaning. All her reflexes were present and she was practically conscious on return to bed. This time the post-operative course was uneventful. There was no urinary disturbance or melaena.

This patient had a third-stage thoracoplasty two weeks later. The dose of *d*-tubocurarine chloride was reduced to 2 mg., which again produced complete ptosis and respiratory arrest, which this time lasted for five minutes.

Remarks

The hypersensitivity to *d*-tubocurarine chloride shown by this patient on the occasion of her first operation was confirmed and placed beyond all possibility of reasonable doubt at the second and third operations. The difference between the dosage (1 mg.) accounted for the slightly less

severe reaction on the second occasion. It is interesting to speculate what would have happened if a preliminary small dose had not been administered.

Neither of these cases gave any history or symptom suggestive of myasthenia gravis, and the second has since been examined most carefully without disclosing any sign of this disease.

Discussion

For reasons which have been repeatedly stressed (Gray, 1947) we consider that *d*-tubocurarine chloride should be given before the induction of anaesthesia, and these two cases further urge the importance of this observation. But it is clear that the primary administration of this drug, whether at induction or during the course of an operation, should always be preceded by a trial dose not exceeding 5 mg. for the healthy adult. Its effects should be observed for at least two minutes before proceeding with the further administration. In the conscious patient a "normal" reaction to the trial dose is evidenced by a sensation of lassitude and fatigue and difficulty in keeping the eyes open; very rarely there may be a slight and transient diplopia.

Any ptosis that occurs should still be under voluntary control. If it is not, or if there are other signs of a more than usually severe reaction—e.g., persistent diplopia, dysarthria, or dysphagia—any subsequent dose should be reduced significantly. It does not need to be emphasized that if there is respiratory embarrassment after this small dose (Case ?) further administration should be abandoned.

Summary

The factors controlling the dosage of *d*-tubocurarine chloride are reviewed and two cases of extreme hypersensitivity are described; the advisability of the preliminary administration of a trial dose is stressed.

Medical Memoranda

Perforation of the Posterior Fornix and Pouch of Douglas during Coitus

The following case is presented because of the rarity of this type of injury.

CASE HISTORY

The patient, a woman aged 57, had had eight children, the eldest being 37 and the youngest 15. She had travelled to the hospital by bus, and was seen at the receiving room. The history was that whilst having intercourse about one hour previously she experienced a sharp pain in the vagina and had since been bleeding slightly per vaginam. At the same time she felt a dull ache in the lower abdomen and this had persisted. Since the birth of her last child she had not menstruated. Intercourse had last been indulged in about twelve months previously.

On inspection the patient was pale and apprehensive but was not shocked. The pulse was 86, temperature 97.4° F. (36.3° C.), respirations 18, and blood pressure 110/80. The lower abdomen was resistant but not rigid. There was some tenderness over the hypogastrium. Vaginal examination revealed that there was a transverse tear in the posterior fornix about 1½ in. (3.75 cm.) in length, and a loop of intestine was felt to be lying in the wound. There was a trickle of blood from the vagina. She was placed in the left lateral position and a Sims speculum inserted. The vault of the vagina was examined, and a loop of small intestine was seen to be prolapsed through the tear.

During the examination the patient suddenly collapsed. She became grey, the pulse was almost imperceptible, and the blood pressure fell to 0. The examination was discontinued, and within a few minutes she recovered and the blood pressure rose to its former level.

In view of the unusual type of injury and the possibility of it having been caused by an instrument of some sort, exploratory laparotomy was performed, the abdomen being opened by a midline incision. About 3 to 4 oz. (85 to 114 ml.) of blood was found in the pouch of Douglas, but there was no bleeding-point. The intestines were undamaged. The tear in the pouch of Douglas was not visible but was easily found with the finger. The uterus was small and anteverted, and both ovaries were healthy. They were not unduly atrophic.

The blood was mopped up and a drainage-tube inserted through the rent in the pouch of Douglas into the vagina. It was secured to the posterior wall of the uterus by one stitch of No. 0 catgut. The abdomen was then closed in the usual manner. A prophylactic course of penicillin and sulphonamide therapy was started after operation, and apart from a slight "spike" on the second night the patient remained afebrile. Nothing drained from the drainage-tube, which was removed on the third day. Vaginal examination on the 18th day revealed a transverse scar in the posterior fornix. Cerebral sepsis was complicated by a stitch abscess, and the patient was discharged from hospital on the 23rd day.

A few days after operation she gave further details of the mishap. Her partner was not her husband but a man aged 30. She insisted that normal coitus had taken place in the dorsal decubitus position, and that no bizarre or unusual practices had been indulged in. She stated that her partner had been very excited, and she thought he had used too much force.

DISCUSSION

Minor injuries of the vaginal introitus due to defloration are not uncommon, and these occasionally require medical attention. More serious injuries of the vagina are rare, and Neugebauer in 1899 collected from the world literature 15 cases of injuries to the vagina sustained during coitus. Thirty-eight of these showed a posterior fornix injury. Since then four more cases of injury to the posterior fornix have been reported.

Of these 42 cases only four had the pouch of Douglas opened, and only one of these four had a prolapsed loop of intestine. Three of the four cases occurred in rape: children, two being 8 years old and one 15 years old. All three patients died—two being murdered, and one dying of generalized peritonitis. The fourth case, reported by Fischer (1928), occurred in a woman of 26 who had had both ovaries removed for inflammatory disease some years previously. The patient recovered after laparotomy. The common factor in all the cases was a thin vaginal wall, due either to post-menopausal atrophy or to pre-pubertal immaturity.

The condition probably never occurs in a normal woman in child-bearing years, and should such a patient show a rupture of the pouch of Douglas one should bear in mind the probability of an instrumental injury due either to an attempt to procure abortion or to unusual sexual practices.

My thanks are due to Mr. Lewis Graham for his helpful advice in the management of this case, and to Dr. H. Notholds and Mr. Alistair Gunn for permission to publish the case history.

A Century of Public Health is the title of a small brochure which is being circulated abroad by the organizers of the Public Health and Municipal Engineering Congress and Exhibition which will be held at Olympia, London, from Nov. 15 to 20. The brochure traces progress from Edwin Chadwick and the first Public Health Act in 1848 to the present time. It attributes the substantial progress made first to the awakening of the social conscience and political instincts of the nation, and then to the advancement of science and the native skill and ingenuity in engineering. "If many years now," the writer states, "behind the public engineering there has been the forceful backing of engineers and inventors eager to direct their knowledge, skill, and resources to the betterment of the public health and municipal engineering of the world. Nowhere else in the world was the ground more fruitful for development; here was a highly industrialized country well on the van of progress in civil, mechanical, and electrical engineering well equipped to adapt itself to the needs of the crowd of industries which industry itself was creating." It is ten years since the Public Health Congress and Exhibition were held in Berlin, and the industries which exist largely for the public health and municipal engineering services will have many new developments to show.

Reviews

TUMOURS

Pathology of Tumours. By R. A. Willis, D.Sc., M.D., F.R.C.P. (Pp. 992; 500 illustrations. £3 3s., postage 1s. 6d. extra.) London: Butterworth and Co., Ltd. 1948.

This new book—indeed a *magnum opus*—will be welcomed not only by pathologists, to whom it will prove an indispensable aid beside the microscope, but as a work of reference by clinicians and all who are interested in tumours. In scope and format the volume superficially resembles the well-known *Neoplastic Diseases* of Ewing, which, however, was last edited in 1940; its author is now dead and the time is ripe for a fresh work on the subject. Professor Willis's book is the outcome of many years of study, formerly and mainly at Melbourne and more recently at the Royal College of Surgeons. Those familiar with his earlier work on *The Spread of Tumours in the Human Body* (1934), and remembering his balanced grasp and comprehensive knowledge of tumours and their habits, will know what to expect here.

The earlier part of the book, comprising about one-fifth, is on the general features of tumours and includes a survey of their statistical study and an up-to-date account of experimental carcinogenesis. In the rest the author discusses the regional aspects of the subject. He is lucid, unequivocal, and often challenging; he treats controversial topics with a refreshing dogmatism tempered with honesty and scepticism and richly illustrated from his own experience. Many will disagree with his opinion on some subjects—for example, the position of the angiosarcomas in the hierarchy of neoplasms, and his including Hodgkin's disease among the tumours of lymphoid tissue. But whether this condition is, as Willis insists, a form of sarcoma or whether it is, as more would agree, a granuloma cannot at present be decided. Willis regards all tumours of the lymphoid tissue as related variants of one disease—a simplification of the reticulates that further study alone will justify or refute.

A novel and welcome feature of the book is the inclusion in each section of a paragraph or two on the incidence of the tumour under discussion in animals other than man; it is evident that the author has ranged widely outside human pathology. There is a bibliography at the end of each chapter with guiding notes to the more important or more useful papers listed. Excellent photomicrographs profusely illustrate the text, and every pathologist will be grateful for the author's concentration upon the less familiar types and their variations at the expense of those commonly depicted in current textbooks.

There can be little doubt that this volume will be most useful and popular. In future editions Professor Willis might consider the advisability of gathering together information on the glomus and carotid-body tumours in the light of recent work on these structures. We hope that some sections will be enlarged—for example, that on carcinoma of the suprarenal cortex.

DOROTHY S. RUSSELL.

MEDICAL SCIENCE

The Background of Therapeutics. By J. Harold Burn, M.D., F.R.S., Oxford Medical Publications. (Pp. 367; illustrated. 22s. 6d.) London: Geoffrey Cumberlege (Oxford University Press), 1948.

Therapeutics has made great advances in recent years and the therapeutic nihilism of 50 years ago is little more than a memory. The subject matter of pharmacology includes much of the work on which these advances depend, although it has not all been done by pharmacologists. If pharmacological teaching is to be a really live force it must describe not only the results of the work that has been done but also the methods by which these results were obtained. Some writers have tended to present the subject as a collection of facts with scarcely more logical connexion than the facts of anatomy. The new book by Professor J. H. Burn is a welcome contrast to this dull but practical type of book. He has written it for those engaged in teaching clinical medicine, and he takes them straight to the frontiers of knowledge.

The subjects chosen for discussion are the recent advances in physiology, pharmacology, biochemistry, and clinical science which have had most effect on therapeutics, but the excellence of the book depends not so much on the subjects reviewed as on the stimulating way in which they are presented. Professor Burn describes experimental facts in detail and encourages the reader to think out their significance for himself; he provides the clues, but in many cases the solution of the mystery is still unknown. In the first chapter he discusses various unorthodox systems of medicine and the reasons for their success. In later chapters he considers the antidiuretic hormone, thiouracil, antihistamine substances, malaria, sulphonamides, salicylates, folic acid, iron, calcium, oedema, digitalis, theories of anaesthesia, diabetes, and many other things besides. There is a useful summary of recent work on acetylcholine and its relation to myasthenia. The last chapter is called "Statistics Explained," and the list of contents encourages the hope that this is achieved in three pages: actually the chapter occupies nearly a dozen pages. Professor Burn presents all these subjects in a way that will surely provoke thought, stimulate discussion, and lead on to new knowledge.

In the preface he says that when he visited America in 1942 and 1943 he was strongly impressed by the great interest that physicians show in laboratory and clinical research. He believes that this interest has been fostered by the growth of professorial units staffed by clinical workers who spend a substantial part of their time in laboratories, where they learn that the discovery of new facts is not only something which they themselves can do but is also very well worth doing. "The great need in clinical medicine to-day is of young people trained for at least two, and preferably for five, years in the laboratory." Professor Burn has done more than anyone else in Britain to train young medical research workers in the inspiring atmosphere of an active laboratory. His new book will extend his influence over wider circles.

J. H. GADDUM.

RETROPUBIC SURGERY

Retropubic Urinary Surgery. By Terence Millin, M.Ch., F.R.C.S., F.R.C.S.I. (Pp. 203; 163 figures. 25s.) Edinburgh: E. and S. Livingstone, 1947.

The author does not confine himself to discussing only prostatectomy but gives an account of the retropubic route as a means of approach for other operations in urological surgery such as the repair of traumatic rupture of the posterior urethra, the relief of stress incontinence in women, and occasionally the opening of a prostatic abscess. But the main interest of this book lies in Mr. Millin's method of prostatectomy. A reviewer must consider and answer two questions—first on the author's success or failure in clearly expounding his methods, and secondly on the value of the methods themselves. The first is much easier to answer than the second. Mr. Millin gives an excellent account in clear English—and clear English is not a characteristic of surgical textbooks—of his operative technique, and with the help of the numerous and clear illustrations no reader should have any difficulty in understanding his methods. Indeed, the whole production of the book is far above the average and the publishers are to be congratulated on producing such a handsome volume in these times of economic stress.

Too little time has elapsed to allow of any final verdict on the value of retropubic prostatectomy. Mr. Millin is right in saying that no surgeon can remain content with the older operation, which infringed several of the accepted principles of surgery. There can be no doubt that in his hands, and assisted by his well-trained team, the retropubic method has given good results, but it remains to be seen whether a wider use of it for a longer time will lead to a lowering of the mortality of prostatic surgery. Both transurethral resection and the operation advocated by Harris have been hailed in the past as the methods *par excellence* of dealing with prostatic obstruction, but some of those who formerly spoke of them with the greatest enthusiasm have now learnt that both techniques have their limitations. It may well be that retropubic prostatectomy is destined to survive as the method of choice, but time alone can tell. More and more surgeons are undoubtedly adopting this technique.

KENNETH WALKER.

MALNUTRITION OF NERVOUS SYSTEM

Nutritional Disorders of the Nervous System. By John D. Spillane, B.Sc., M.D., M.R.C.P. Foreword by George Riddoch, M.D., F.R.C.P. (Pp. 280; illustrated. 20s.) Edinburgh: E. and S. Livingstone. 1947.

The study of the effects of malnutrition of the nervous system during the recent war has shown how complex the problem is and how much we have still to learn. The time was therefore appropriate for a balanced survey of the present state of our knowledge, and Dr. Spillane has provided one. He describes first the vitamins of the B group and then such well-recognized syndromes as pellagra, beriberi, polyneuritis, Wernicke's encephalopathy, encephalopathy caused by nicotinic-acid deficiency, and subacute combined degeneration of the spinal cord. He next discusses the mixed and complex clinical pictures presented by cases of nutritional neuropathy in warm climates and in wartime, and finally gives an account of his personal experiences among German and Italian prisoners of war and Polish refugees.

The result is a book full of interesting clinical data interspersed with valuable critical reviews of the pathogenesis of the various syndromes, but the method of presentation imposes work on the reader, who has himself to correlate the discussions of the same topic which appear in the different sections. Dr. Spillane has often wisely avoided dogmatism. His book will therefore appeal more to the critical student than to the reader who demands a predigested diet, but perhaps a little mental roughage is not a bad thing.

W. RUSSELL BRAIN.

SENSORY DISCRIMINATION

Anatomical Pattern as the Essential Basis of Sensory Discrimination. By Prof. W. E. Le Gros Clark, F.R.S., F.R.C.S. Forty-ninth Robert Boyle Lecture, May 29, 1947. (Pp. 16. 1s.) Oxford: Blackwell Scientific Publications. 1947.

In his Robert Boyle Lecture Prof. Le Gros Clark interprets afresh the anatomical basis of sensory discrimination in the light of knowledge derived in recent years from studying the anatomical patterns of sensory systems. Though brief, it is valuable as a very clear and concise review of a subject to which Prof. Le Gros Clark has himself contributed so significantly. He reminds us that certain predictions can be made about the probable anatomical basis for sensory discrimination from the fact that only one kind of impulse can be transmitted along a nerve fibre. The relevant discoveries support these predictions—namely, (1) that the sensory receptors provide a system of peripheral analysers whereby the various stimuli within a sensory modality are sorted out in the first instance; (2) that the nerve impulses generated by receptors within each modality become segregated on their way to the higher functional levels of the nervous system; and (3) that they are eventually projected on to centres that are organized in spatial patterns. The precise and definite topographical relations exhibited by the intrinsic elements in these cortical centres must form ultimately the structural basis for sensory discrimination. Prof. Le Gros Clark reviews each sensory system in turn, with special emphasis on the visual mechanisms. His attempt to relate the six-layered type of geniculate body to the trichromatic theory of colour vision is briefly referred to. He considers that the intricate sensory plexuses in which the afferent fibres become appropriately segregated are essential prerequisites for sensory discrimination, and he concludes by discussing the problem presented by their morphogenesis.

The interpretation proposed by Prof. Le Gros Clark raises as many problems as it appears to solve. Sensory discrimination regarded as though it were a separate faculty of the brain would certainly seem to demand a corresponding anatomical "discrimination" as its basis, especially in regard to the peripheral analysers and their centripetal pathways. However, discrimination is intimately related to all the other complex activities which are subsumed under the general term perception. So far as an immediate problem is concerned this can be a great advantage, if it could be shown that separate anatomical structures dealt with the various "units" of perception—such as the appreciation of movement, contour, form, and direction of the first synthesis being left to some

higher centre. But in the case of vision, at least, the striate cortex and its afferent paths are themselves capable of the whole range of perceptual organization. Thus the same structural parts in the brain which are to be regarded as the final determinants of sensory discrimination must also be capable of explaining the other aspects of perception. The problem is rendered the more difficult in that many of the latter, such as sense equivalence (an object in the visual field always remains the same object despite incessant changes in visual fixation), seem to require almost the opposite kind of anatomical basis to that which must be presumed essential for sensory discrimination.

PETER BISHOP.

INTRODUCTION TO MEDICAL GENETICS

Genetics in Relation to Clinical Medicine. By F. A. E. Crew, M.D., D.Sc., Ph.D., F.R.S., F.R.C.P.Ed. (Pp. 111. 10s.) Edinburgh and London: Oliver and Boyd. 1947.

The student of human genetics draws on a wide range of biological data derived from animal and plant breeding, experimental embryology, and serological research. He relies on statistical methods to verify his hypotheses to a far greater extent than does the practical breeder of stocks and crops or the investigator doing designed experiments in the greenhouse or laboratory, who can control matings and standardize the conditions of his experiments. The medical student needs both a book to which he can turn for a simple exposition of statistical methods appropriate to the investigation of human material and a lively appreciation of the bearing of modern experimental research in the field of development and heredity on the problems of health and disease. Prof. Crew's book, like those of Frazer Roberts and E. B. Ford, is primarily on results and interpretations. He brings to his task the equipment of a medical training and a distinguished career of research in animal breeding before undertaking new responsibilities as Professor of Social Medicine in the University of Edinburgh.

The book fills a real need, and it is packed with lively information and pertinent examples of a wide range of biological phenomena relevant to medical problems. Prof. Crew's trenchant style as a platform speaker is less adapted to easy reading than to congenial hearing. One of his great merits is very temperate and imaginative appreciation of the complexity of the relations between nature and nurture as they affect the interpretation of medical problems—a quality all the more praiseworthy because it is only too rare among those who have devoted much of their time to the simpler problems of animal and plant breeding.

The book incorporates much recent work in the rapidly widening field of human genetics, including for instance a concise and lucid account of Prof. Fisher's theory of the inheritance of the rhesus antigens, and it is a useful work of reference—though an index would enhance its value. The rapidity of the advance of human genetics depends however on the keen observation and acumen of the general practitioner with the ready co-operation of the specialist in genetics, and too much emphasis cannot be given to Prof. Crew's plea on p. 83: "What are needed more than anything else for the speedy advancement of our knowledge of human genetics in its relation to clinical medicine are (1) the country-wide systematic preparation of pedigrees by genetically informed and interested medical practitioners, and (2) a storehouse where these can be received, pooled, and interpreted."

J. A. H. WATSON.

DEAF CHILDREN

Opportunity and the Deaf Child. By Irene R. Ewing, O.P.F., M.Sc., and Alex W. G. Ewing, Ph.D., M.A. With an appendix by Molly Sefton. (Pp. 252. 9s. 6d.) London: University of London Press, Ltd.

A child unable to understand what is said to it because of defective hearing suffers a handicap that is as misleading as it is serious—misleading because of the ease and frequency with which the real nature of the handicap is overlooked, because at an age when mental development should be continuing a process as physical development the principal element of communication is denied the deafened child. From their wide and unique experience the Ewings have written a book

andbook in response to numerous requests from doctors, parents, and teachers of deaf children. It should be read by all interested in the welfare of deaf or hard-of-hearing children. Its value is further enhanced by an account by Molly Sefton of how the world appears to a deaf child, and the full and fascinating story she tells of her education is a great tribute to her teacher, Mrs. Ewing.

Starting with a general survey of the education of the young deaf child and the methods of testing hearing in young children, the Ewings describe their experience with a clinic for young deaf children and their views on the development of speech in both normal and hard-of-hearing children. They compare the normal and deaf child and give a guide to the training of the deaf child in its earliest years. They discuss the problem of the hard-of-hearing as opposed to the deaf child and consider the value of hearing-aids. They then discuss deaf children who suffer from additional handicaps, and fully describe the schools that specialize in the education of these children. They stress the usefulness of lip-reading and the dual importance of getting speech into as well as out of the deaf child.

In this small handbook of 250 pages the Ewings have included a full and practical account of all the problems that confront the parent, teacher, and doctor who may be faced with the upbringing of a deaf child. It is a striking testimony to a lifetime's study, and it is likely to become a standard work for all who are interested in deaf or hard-of-hearing children.

TERENCE CAWTHORNE.

PAIN IN THE BACK

Chronic Structural Low Backache due to Low-Back Structural Derangement. By R. A. Roberts, M.B., Ch.B., D.M.R.E. (Pp. 105; 137 illustrations on 46 plates. 45s.) London: H. K. Lewis and Co. 1947.

This book is a valuable contribution to the study of a common but little understood complaint the sufferers from which have too often been labelled as neurotic or even malingers, especially in the Services. In the greater part of the book the author describes cases of low-back pain in which careful radiographical study has revealed lesions of the "pars interarticularis" of a lumbar vertebra. The author believes that the lesion, which may in some cases be congenital, is more often the result of strain leading to bone absorption like that seen in cases of "march fracture," reossification sometimes but not invariably following. A striking feature in many of the cases described is the association of visceral disorders, haemorrhoids, dysuria, albuminuria, haematuria, and even symptoms attributed to colitis, appendicitis, or cholecystitis which failed to yield to the usual medical or even surgical measures. Often the sufferer was referred to the psychiatrist and a diagnosis of anxiety state arrived at, even in men of fine type. The detailed account of these cases and of the various diagnoses, which led often to discharge from the Service with the stigma "neurotic," leaves the reader with an uncomfortable feeling of having been similarly in error. The author wisely emphasizes that a careful inquiry into the history of the cases is essential and may result in fewer being referred to the psychiatrist. He amply illustrates the desirability of examining the spine radiographically in doubtful abdominal cases and makes clear the risk of manipulation in treating chronic backache.

The second part of the book is on the study of neurovascular and visceral symptoms. The author suggests that oedema of soft tissues as a result of strain is a cause of pain and the precursor of nodule formation and adhesions in fibrositis. This idea calls to mind the striking results sometimes obtained from simple acupuncture as described by Sir James Simpson, a method now generally abandoned but which may have the same effect in relieving tension in inflamed structures as procaine injections or more elaborate measures. The book is illustrated by admirable reproductions of radiographs, and explanatory diagrams assist in their study. We cordially recommend it to general practitioners as well as to specialists in orthopaedics and rheumatic disorders, for even though the author's conclusions may not meet with universal acceptance they cannot fail to prompt the reader to further study and investigation.

C. W. BUCKLEY.

THE DIFFICULT CHILD

The Doctor and the Difficult Child. By William Moodie, M.D., F.R.C.P., D.P.M. Second edition. (Pp. 231. 52 or 11s. 6d.) New York: The Commonwealth Fund. London: Geoffrey Cumberlege (Oxford University Press). 1947.

The appearance of the second edition of this book is welcome, for it is one of the most sensible and informative that have been written on the subject. The occurrence of the second world war may have led some people to expect far-reaching changes in the book, since it might have been thought that the problems of child development would have greatly altered. Yet in spite of the bombing and evacuation, of family disruption and interference with education, the essential pattern remains the same. The stable child seems to take everything in his stride and adjusts himself without difficulty to abnormal conditions, whether these be sleeping in shelters or removal from the town to the country. To the unstable child similar experiences may be devastating, and he reacts to them by enuresis, sleeplessness, nightmares, or even by lying and stealing, as he has always done in response to difficulties. Bombing would seem to have been the least disturbing of wartime influences and interruption of education the worst, though the broken homes resulting—first from the departure of the father and secondly, too often, from his return—have made life more difficult for the child.

The author has added a new chapter on play therapy showing how important and fruitful this method may be in experienced hands for the psychological investigation and treatment of young children. A second new chapter is on the full constitution of the child-guidance team in the light of 20 years' experience. For the rest, the book is much as it was. In the first part the author discusses the recognition, diagnosis, and treatment of problem children on general lines, and in the second the various manifestations of mental difficulty in children such as lying and stealing, sex difficulties, speech defects, fits, anxiety, nightmares, and enuresis. As is usual with Commonwealth Fund publications the book is admirably produced, and all dealing with children should take advantage of this exposition of Dr. Moodie's experience and clarity of mind.

R. G. GORDON.

SCHIZOPHRENIA: AN AUTOBIOGRAPHY

The Kingdom of the Lost. By J. A. Howard Ogdon. (Pp. 256. 10s. 6d.) London: John Lane, the Bodley Head, Ltd.

The description by a schizophrenic of the experiences he has undergone during the acute phase of his illness is always a matter of great psychiatric interest, and especially so when the patient is a man of ability and learning. To these advantages Mr. Ogdon adds those of very unusual powers of introspection, a clear memory of past experience, and a gift for graphic writing. There can be little doubt that his book will be of interest to the intelligent lay public. To the psychiatrist it is likely to become a classic among self-descriptions.

Mr. Ogdon's illness lasted for about three years, and during this time he had several phases when symptoms were florid, each of which passed off leaving residual disabilities. A striking feature throughout was the development of symbolizations, by which every person, almost every object in his neighbourhood, numbers, colours, letters of the alphabet, and so on, came to have a symbolic meaning with the force of reality. Mental and physical activities were tied down by compulsions and inhibitions associated with these symbolic meanings. His account of the "heroic" phase, in which the patient felt that he controlled the world by his power over its symbols, makes fascinating reading.

Mr. Ogdon believes he is almost unique among schizophrenics in having cured himself without medical aid. Of the reality of the cure there can be little doubt, although the self-conscious psychiatrist is likely here and there to pick on a sequence of thought or a mode of expression that bears a schizophrenic stamp. Nor can there be much doubt that Mr. Ogdon did a very great deal to help himself, though once again those who are not disciples of Yoga or of Baudouin will be unable to follow him all the way in what he says. The main help that

these mental disciplines provided was probably not in halting the progress of the disease, which seems to have undergone a spontaneous remission, but in enabling the patient to rid himself of residual symptoms. Mr. Ogdon's criticisms of the law relating to certification and of the standards of treatment meted out in mental hospitals will be read with sympathy. He may rest assured that, in the second of these, matters are changing very rapidly, and a change in the first is inevitable in the not very distant future.

ELIOT SLATER.

WAR MEDICINE

Inter-Allied Conferences on War Medicine 1942-5. Convened by the Royal Society of Medicine. Hon. Editor: Major-General Sir Henry Lethbridge Tidy, K.B.E., M.D. Assistant Editor: J. M. Browne Kutschbach, M.B., B.Ch., D.P.H. (Pp. 531. 50s.) London: Staples Press. 1947.

Sir Henry Tidy is to be congratulated on his collecting together in this volume various papers read at the Inter-Allied Conferences on War Medicine held between 1942 and 1945. Perhaps to those who served as medical officers—and the book will have little appeal to those who did not—the section entitled "Active Operations" will be the most interesting. The very names, which had at the time few but the most odious associations, have been endowed by the passage of years with a nostalgic attraction. Brigadier Wallace's characteristic account of the battle of El Alamein and the advance through Daba, Fuka, Matruh, Sidi Barrani, Sollum, Bardia, Tobruk, and on to Tripoli; the R.A.M.C. at Arnhem; the personal adventures of medical officers by sea and by land in Europe, Africa, and Asia—it is to these that the ex-Service doctor will turn with a feeling of satisfaction that he had, in however humble a capacity, some share in these experiences.

The papers on organization and professional subjects have an interest that is different, but no less. The control of dysentery and malaria, the studies of infective hepatitis, the organization of the blood-transfusion service, and the treatment of neuro-surgical, vascular, and maxillofacial injuries are all discussed. The lessons learned during 1914-18 were largely buried in the *Medical History of the War*, and in 1939-45 there was little time or inclination to disinter them from a work of such forbidding magnitude. Many of the lessons were relearned in the wasteful school of experience and are restated in this small—although unduly expensive—compilation.

R. BODLEY SCOTT.

THE APPENDIX

The Appendix. By R. J. McNeill Love, M.S., F.R.C.S., F.A.C.S. (Pp. 186. 54 illustrations. 12s. 6d.) London: H. K. Lewis and Co. 1947.

It is well known that the London Hospital was the home in this country of the expectant treatment of certain cases of acute appendicitis which is appropriately called the Ochsner-Sherren treatment, thus commemorating the "London" surgeon who popularized the method here. Mr. McNeill Love thoroughly considers the pros and cons of the matter, though the method is widely accepted and practiced nowadays. However, he discusses not only acute appendicitis but all appendicular lesions, and although the book is much smaller than many others on the same subject it is one of the best summaries, especially from the practical point of view. The advice given is always wise and of real value to the surgeon, and the sections on differential diagnosis reveal the author's large experience. We found the chapter on chronic appendicitis particularly interesting and concur with the author's critical attitude towards the varied diagnoses of the condition. While not ignoring the help that x-ray examination may afford, he is especially careful not to let it sway his judgment. There can be no doubt that too many persistent appendices are removed as a result of an x-ray diagnosis unconfirmed clinically and that more discrimination would reduce the number of wrong diagnoses. The numerous illustrations are useful and clear. Altogether this is an admirable contribution to the literature of the appendix, not too long, not too short, not certain at all those points.

NORMAN C. LEWIS

BOOKS RECEIVED

(Review is not precluded by notice here of books recently received.)

The Medical Clinics of North America. Chicago Number (Pp. 299. No price.) Philadelphia and London: W. B. Saunders. 1948.

A collection of papers chiefly on endocrinology.

Diseases of the Chest. By R. Coope, M.D., B.Sc., F.R.C.P. 2nd ed. (Pp. 541. 25s.) Edinburgh: E. and S. Livingston. 1948.

An introduction for students and practitioners.

Textbook of Public Health. By W. M. Frazer, O.B.E., M.D., M.Sc., D.P.H., and C. O. Stallybrass, M.D., D.P.H. 12th ed. (Pp. 571. 30s.) Edinburgh: E. and S. Livingstone. 1948.

This well-known textbook has been brought up to date in the light of the recent Health and Insurance Acts.

An Introduction to Physical Methods of Treatment in Psychiatry. By W. Sargant, M.A., M.B., M.R.C.P., D.P.M., and E. Slater, M.A., M.D., F.R.C.P., D.P.M. 2nd ed. (Pp. 215. 10s. 6d.) Edinburgh: E. and S. Livingstone. 1948.

A general account for the clinician.

Liver Injury. (1) Transactions of the 6th Conference, May 1 and 2, 1947, New York. (2) Transactions of the 5th Meeting, September 26-27, 1946, New York. (Pp. 74 (1), and 127 (2). 5s. each.) New York: Josiah Mney, Jr., Foundation. 1947.

A variety of papers on experimental and clinical aspects of liver disease.

Surgical Treatment of the Abdomen. Edited by F. W. Emery, A.B., M.D., F.A.C.S., and P. A. Wade, A.B., M.D., F.A.C.S. (Pp. 1,026. £5 10s.) London: J. B. Lippincott. 1947.

A textbook, with operative details; includes section on anatomy.

New Biology. Edited by M. L. Johnson and M. Abercrombie. (Pp. 159. 1s. 6d.) West Drayton: Penguin Books. 1948.

Includes articles for the layman on statistics, hybrid vigour, and human teeth.

American Medical Research Past and Present. By R. H. Shryver, Ph.D. (Pp. 350. 14s.) London: Geoffrey Cumberlege. 1947.

A history of the growth of medical research in the U.S.A.

Emergency Surgery. By Hamilton Bailey, F.R.C.S., F.A.C.S., F.I.C.S., F.R.S.E. 6th ed. Part 1. (Pp. 180. 21s.) Bristol: John Wright. 1948.

The first of five parts in which the sixth edition of this well-known textbook is being published.

Normal and Abnormal Psychology. By J. E. Nicole, O.B.E., D.P.M. (Pp. 96. 8s. 6d.) London: George Allen and Unwin. 1948.

A concise account of normal and abnormal psychology for students.

Manual of Clinical Therapeutics. By W. C. Cuthbert, M.D. 2nd ed. (Pp. 712. 25s.) Philadelphia and London: W. B. Saunders. 1948.

A concise manual for house-men and practitioners.

Introduction to Medical Science. By G. L. Muller, M.D., D. E. Dawes, R.N., M.A. 2nd ed. (Pp. 580. 20s.) Philadelphia and London: W. B. Saunders. 1948.

An introduction to pathology and medicine for students.

Communicable Diseases for Nurses. By A. G. Brown, M.S., M.D., F.A.C.P., and E. B. Pihant, R.N. 6th ed. (Pp. 20s.) Philadelphia and London: W. B. Saunders. 1947.

A general account for nurses.

Minor Surgery. By F. Christopher, B.S., M.D., F.A.C.S. 4th ed. (Pp. 1,058. 60s.) Philadelphia and London: W. B. Saunders. 1948.

A textbook, with lists of references and many illustrations.

Standard Radiographic Positions. By N. Davis, M.S.R., and U. Leisberg, M.S.R. 2nd ed. (Pp. 223. 2s. 6d.) London: E. & S. Livingstone. 1947.

Many diagrams illustrate the positions.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY APRIL 24 1948

THE PLEBISCITE

The Council of the B.M.A. met last week to consider the Minister's statement in Parliament and the answers he gave to questions put to him by the B.M.A. It decided to hold an immediate plebiscite, the terms of which are described elsewhere in this issue. Some members of the profession may argue that another plebiscite is not necessary, and probably all will feel some reluctance at having once more to define their attitude to the National Health Service Acts of 1946 and 1947. It is, however, essential to recognize that the profession is now faced with a new situation, and before the Council can take any further step it is imperative that it should know whether the medical profession considers that the new proposals of the Minister of Health go far enough to meet the overriding objections to the Act which induced such an overwhelming proportion of doctors to disapprove in February of the Act in its present form. The democratic mechanism of the plebiscite may be cumbersome, but those who may hesitate to vote again should remember the heavy burden of work that falls upon those at B.M.A. House who have to conduct this operation. We would therefore urge once more all medical men to return their plebiscite forms and to vote with a full sense of responsibility towards the present situation.

In making up their minds how to vote medical men will ask themselves first whether the Minister's proposals are in fact sufficient to safeguard the essential freedoms of Medicine. They should also take into account the reaction of Parliament and the Press to the temperate and conciliatory observations made by Mr. Bevan in the House of Commons on April 7. If this second plebiscite should provide an adequate majority to justify collective opposition to service under the Act, public opinion will play a large part in determining the result. We must therefore take note of the fact that public opinion, as expressed by those who represent their constituents in Parliament and by responsible daily and weekly newspapers, considers that Mr. Bevan has made a conciliatory move towards a solution of present difficulties. It is recognized that this move has been made as the direct result of the enormous vote of no confidence in the present Act given in the plebiscite earlier this year. The Government had to take this into account and has in consequence modified its policy. Doctors must now ask themselves whether the modifications go far enough to remove their underlying fears of the Act in its unmodified form.

In a leading article in the *Journal* of Dec. 20 last year we stated that "preoccupation with financial and other details, important as they are, for medical men have their

living to make; must not obscure the main issue which the medical profession now has to face." This issue, we suggested, was summed up in the first of the principles enunciated by the Negotiating Committee in 1945. It is well to repeat the words of this:

The medical profession is, in the public interest, opposed to any form of service which leads directly or indirectly to the profession as a whole becoming full-time salaried servants of the State or local authorities.

This was the first and cardinal principle formulated by the Negotiating Committee and accepted by the profession. The Minister's new proposals must be measured against this principle. At the last Special Representative Meeting the Chairman of Council, Dr. H. Guy Dain, discouraged the Representatives from driving themselves "into the undesirable position of establishing a list of priorities in their demands." He begged the meeting "not to enter into a Dutch auction or a bargain sale, but to keep in mind the *maintenance of freedom and independence*." Dr. Dain on the same occasion said: "We doctors want a health service. We want our services to be available to all who need them. We are ready to enter into any discussion directed to making it possible for the medical profession to co-operate with the Government. If the Government can show us other ways, new ways, of preserving our independence, we are willing to listen."

The policy of the B.M.A. has always been clear and never more clearly stated than in these words of its principal spokesman, the Chairman of Council. Its objections are not to the Act as a whole, not to a general medical service for the nation, but to entering a service which in the words of the above principle "leads directly or indirectly to the profession as a whole becoming full-time salaried servants of the State or local authorities."

Doctors must now ask themselves whether the Government's promised Amending Bill directed towards the prevention of the introduction of such a service through Regulations under the present Act does meet the profession's fundamental objection as expressed in the first of the principles of the Negotiating Committee. If we are to be fair we should recognize that Mr. Bevan has agreed to put on the Statute Book what he has hitherto given only as an assurance, and which could not be binding on any future Minister of Health. We may recall, too, that during the Second Reading Debate on the Bill Mr. Key, then Parliamentary Secretary to Mr. Bevan, said that the Government recognized that a full-time salaried service was incompatible with free choice of doctor. Mr. Key then said: "We regard the free choice of doctor by the patients as being the more important principle, and, therefore, we put forward a compromise"—the compromise of payment partly by capitation fee and partly by salary. Mr. Bevan's promised Amending Act must be linked with his abolition of the universal basic salary. In his replies to the B.M.A.'s questions he is, too, prepared to consider the conditions applying to those who would like to opt for a basic salary. We recall that Mr. Willink proposed that the general practitioner should be in contract with the Central Medical Board—a central body which would also appoint the general practitioner wishing to enter the public service,

Since 1945 the position has changed. First of all, the practitioner is now in contract not with the Central Medical Board but with the Local Executive Council. It was then proposed that the Local Executive Council should have the principal voice in selecting a man for a vacancy in the public service on the advice of local doctors. In his replies published last week Mr. Bevan stated that, with certain obvious limitations, the practitioner will have the right to choose his partner or assistant. "Every doctor," Mr. Bevan states, "will be free to practise where he chooses, unless it is one of the areas where the Medical Practices Committee decide no more doctors are needed in the Service. In all cases except the latter 'consent' will be automatic."

Faced with these facts, the general practitioner will have to consider whether he is now offered adequate safeguards against becoming a full-time salaried servant of the State. In the absence of adequate safeguards the majority of general practitioners believe that retention of the custom of buying and selling practices is the only guarantee of freedom. Mr. Bevan continues to refuse to amend those Sections in the Act which abolish the buying and selling of public practices. It is clear that the Government will not give way on this point. The advantages to the doctor of this custom are many and considerable, and have been often discussed in these columns. The principle behind this custom is the safeguard afforded to the practitioner against becoming a full-time salaried servant of the State. General practitioners must now decide whether, with the abolition of this custom, the Minister's new proposals safeguard their essential professional freedom. In coming to a decision on this matter they will reflect that public opinion as expressed by all political parties is not in favour of the buying and selling of public practices in which the practitioner receives his remuneration from State funds. As our correspondence columns have shown, there are some young doctors who, while voting against the Act in its present form, consider that this custom now offers financial obstacles to the young man entering practice. It is important that practitioners should fit all these facts into the general picture in making up their minds on this extremely difficult question.

Mr. Bevan would not agree to the B.M.A.'s suggestion that his scheme for distributing doctors should be postponed for an agreed period in order to determine by experience whether the problem may not, in fact, largely solve itself. Mr. Bevan suggests that the system should be worked for an agreed period and then should be subjected to special review in about two years' time. We understand that the Medical Practices Committee is to draw up a list of areas in which the number of doctors is considered to be sufficient for the population. This will be a difficult task. In the rest of the country the doctor will be free to practise where he likes. The Minister would have been wiser if he had got rid of the objectionable feature of negative direction and substituted for it "positive inducement" to attract men into difficult or undesirable areas; it is true that he has set aside a sum of £400,000 for inducement purposes.

It is Mr. Bevan's refusal to grant the right of appeal to the courts against the decision of the tribunal and the

Minister to remove a doctor from a service open to the whole community. The legal background of this matter is discussed elsewhere in this issue by Dr. A. J. Gosh. While there may be some practical force in Mr. Bevan's arguments for his scheme, and while in practice very few doctors are likely to be affected, his refusal to grant a right of appeal seems to us to infringe a principle fundamental to the law of this country. Any one person should have the right to report a doctor direct to a tribunal composed of three men, two of whom have no legal training or experience to guide them in establishing the facts of a case. In his Andrew Lang Lecture at St. Andrews University on April 4 Lord Macmillan said: "There will soon be a break of the common law left either in England or in Scotland and the Statute-book and the vast volumes of statutory rules and orders will take its place." "No feature," he said, "was more noteworthy in recent social history than the tendency of the legislature to invade increasingly the customary conduct of the citizen's daily life and to regulate by law what was previously left to free choice." On the same day a Resolution was passed at the Annual Meeting of the Bar Council viewing with concern "the formidable growth of administrative and quasi-judicial tribunals" and urging the general council of the Bar "to examine the procedure adopted by such tribunals and make such recommendations as they think fit in regard thereto." Mr. Bevan's machinery may provide that justice will be done, but it is doubtful whether it will make it possible that justice "manifestly be seen to be done."

We have dealt more particularly with those matters which affect general practitioners. Consultants are safeguarded against the introduction of a full-time salaried service by the Minister's promised Amending Act, and in his reply to the first B.M.A. question he states that if any Regulations are made under Section 66 of the Act, which refers to Regulations with respect to the qualifications, remunerations, and conditions of service of officers employed in bodies constituted under the Act, he will exclude from that "any provision for universal whole-time specialist service." His reply to question 6 is that on the appointed day existing hospital staffs will be taken over by the hospital governing boards, and we understand that Boards of Governors will take over the existing staffs of teaching hospitals. Mr. Bevan's reply to the second question is that consultant specialist appointments should in most cases be private. He assumes that existing private pay-bed accommodation "will lie where it is at present"; but he cannot exclude himself or future hospital bodies to future distribution. In his third answer he observes that he has excluded teaching hospitals and that he will be unlikely to exclude a hospital first and then acquire it by purchase. Consultants may have cause to be uneasy about Mr. Bevan's statement on pay-bed accommodation and about his answer to the question relating to the medical committees. It would be more satisfactory if medical committees could elect their representatives on Boards of Governors or Hospital Management Committees. We welcome the assurance from the Minister that medical men will have complete freedom to publish their views on the organization and administration of the Service as well as on clinical matters without any prior consent to do so." As this is something which

fundamental to the essential freedoms of professional life we may hope that the Minister will make this assurance authoritatively secure in the new Amending Act.

When the B.M.A. Council met before the last plebiscite as held it issued a brief statement to every member of the medical profession which ended thus: "It would be lacking in its [the Council's] duty, however, if it did not make abundantly clear to every member of the profession its carefully considered and determined view that the profession should not take service under the Act in its present form." The Council then gave a clear lead to the profession to vote "No." Dr. Dain now (p. 805) states that Mr. Bevan's "concessions present us with a change of situation which makes the new plebiscite necessary." The Council observes that the profession has gained some points and not gained others, and makes this cautiously worded observation: "Bearing in mind that what we have secured falls short of what we sought, the Council's view is that, while progress has been made to that end, the freedoms of the profession are not sufficiently safeguarded." It goes on thus: "Whatever your views, please vote in order that the plebiscite may faithfully represent the views of the profession and guide those whose heavy responsibility it is to act on its behalf."

It is now the duty of every member of the medical profession to weigh the present situation in the balance, and to decide for himself whether the Minister's new proposals give him as an individual, and the profession as a whole, the necessary freedoms without which the individual doctor is unable to practise his profession in an atmosphere of intellectual freedom and in the exercise of full personal responsibility for the care of those persons in the community who seek his indispensable help and advice.

SHORTAGE OF BOOKS

The invention of printing 500 years ago provided the means by which division of the labour of thought could be effected and hence man's knowledge and mastery of his environment rapidly enhanced. Any restriction on the free exchange of opinion must have a harmful effect on the progress of civilized man, and in so far as it affects some communities and not others they will fall behind in what shows no signs of ceasing to be a struggle for existence. It is therefore a matter of concern that doctors and students continue to be hampered in their pursuit of knowledge by the severe shortage of books, and in order to investigate its extent and causes we addressed some questions to publishers, booksellers, and librarians. A report on their replies appears at page 800 of this issue.

The replies reveal that the medical books for which there is most demand are the standard textbooks of clinical and preclinical subjects. According to the evidence of the booksellers and librarians, each of whom was asked to name the 10 books most in demand, we found that those 10 most often chosen comprised 2 textbooks of medicine, 2 of surgery, 2 of pathology, 2 of anatomy, and 2 of applied physiology. This class of books is of fundamental importance to the learning and practice of medicine, yet, as the replies to another question show, these are the books most difficult to obtain.

The replies from the publishers suggested a number of reasons for the lack of books. There seems unfortunately to be no single impediment that could be easily removed, but rather many obstacles interposed between the publisher's desk and the bookseller's shelf leading to delay of publication up to two years—a period, on the average, about two or three times as long as before the war. Lack of paper, binding materials, skilled workers, and machinery are together or variously mentioned as causing the shortage. The export of books abroad—officially encouraged to obtain foreign currency—is also an important cause; one publisher mentions that his exports to the U.S.A. are double those of 1939. There is a great demand abroad for British books, particularly from the Commonwealth and from European libraries ruined in the war. Further, the much greater demand at home aggravates the material scarcity. There are more students receiving all kinds of higher education than ever before, their numbers being increased by young men and women who served in the Forces during the war. Commercial firms are said to be ordering more books. The growing specialization of medicine creates the need for a diversity of works on comparatively limited subjects—a need sharpened by the great scientific advances that were as usual incident to waging war.

The shortage of American books in this country is probably more easily remedied than is commonly known. Books may be imported from the U.S.A. either by authorized importers or by private individuals. The importers have a quota by which their expenditure on these books is limited to the average of what they spent over several years immediately before the war. As the replies from the booksellers and librarians show, the quota is short of the present demand. One reason for this is the increased cost of books, fewer being obtainable for the same permitted expenditure. Private persons, however, are entirely free to import books from the U.S.A. As Lord Chorley said, replying for the Government in the debate on the import of books in the House of Lords on Feb. 18: "Any one can get currency from his bank, give an order to a bookseller in America, and the book will be imported by parcel post. There is no difficulty about it, and many professors and scientists have been importing books in this way."

We may ask why recognized importers should not be allowed to obtain these books in bulk and thereby save the cost of individual packing, postage, and insurance. Presumably the existing arrangements, more costly and troublesome to the individual buyer though they are, save scarce dollars in the long run, but it seems that their efficacy in doing so depends largely on the public's remaining ignorant of them. Far more satisfactory would be to increase the importers' quota to 200% of the pre-war figure, as Lord Balfour of Inchrye suggested in the Lords' debate. Lord Chorley on that occasion said that the President of the Board of Trade was examining the quota system, adding, "And it may well be that as a result there will be some increase in the quota," but he could not hold out the hope that it would be 200%. No report has yet been issued.

To make books easy of access to those who need them has never been more necessary than to-day, and on another

page Mr. Le Fânu records the formation of a medical group within the Library Association. Sir William Osler suggested such a group at the annual meeting of the B.M.A. in 1909, and a similar body called the Medical Library Association in America celebrates its 50th anniversary this year. Though hampered by lack of funds, the medical group is preparing a catalogue of periodicals in medical libraries throughout the British Isles, and has already established a pool for the exchange of duplicates, which the Wellcome Historical Medical Library is administering.

More books and still more books should be produced, yet the restrictions are of such a nature that unless the Government helps to remove them it is unlikely that they can soon be overcome. Official circles do not yet appreciate that the unfettered production of scientific books is vital if this country's intellectual life is to flourish. Foreign currency must, of course, pay for other commodities besides paper, strawboards, cotton, and printing machinery, but many imports in comparison with these are of only trifling significance to the nation's well-being. Men and women should be encouraged through the Labour Exchanges and other means to enter the printing industry. The quota of books importers may obtain from abroad should be increased. Unless the fruits of knowledge are enjoyed when fresh, students will continue to "eram" hurriedly with one eye on the time when their borrowed books must be returned, and the achievements of our scientists, professional men, and technicians will fail to be "on the record" in time.

ACUTE INTUSSUSCEPTION IN CHILDHOOD

A death from intussusception is doubly tragic, for the victim is almost always a fine healthy baby, and the fatal outcome is often the result of an error of judgment. In a most instructive analysis of 100 successive cases which appears elsewhere in this issue Drs. Brenda Morrison and Donald Court show some of the ways by which such tragedies may be avoided. Early diagnosis is of course the most important single factor in saving life. In some cases failure in this may be due to the fact that the diagnosis did not cross the mind of the practitioner who was called in to an ill baby. In others, however, the delay in getting the child into hospital can be more justifiably ascribed to the difference between the presenting signs in actual life and that classic picture reproduced in textbook after textbook with a fidelity that arouses suspicion.

The differences from the classic description seen in this series are many and important. Vomiting was an early and constant symptom, occurring in 90% of cases; blood from the rectum (the crucial diagnostic point of the textbook) appeared during the critical first day in little more than half of them, and was altogether absent in a quarter. The main point for the family doctor is that sudden abdominal pain in a previously healthy baby justifies its immediate and urgent admission to hospital, where it can be investigated, closely watched, and, if necessary, operated upon by those with special experience. A dangerous reason for delay is the presence of fever, which may suggest an infection. Yet in half the cases the temperature was considerably raised, between 100° and 104° F. (37.9° and 40° C.).

On arrival at hospital the history is taken with the utmost care, and need be from a parent specially fetched. The child must be under close and continuous watching and care. The most exact examination, establishes the diagnosis. The

authors do not advise barium enema as an aid to diagnosis, and on this point some may differ from them. An admittedly small experience, they consider that the procedure may be harmful to the child, though they note the excellent results reported by other workers who use enema as a form of treatment, with or without laparotomy. The subject of the treatment of intussusception however, hardly falls within the scope of the article; the authors mention two most important points. The first is that the operation should not be begun unless an intravenous drip is running, and the second that the anaesthetic should start with the surgeon standing ready by the table. This paper emphasizes once again the need for checking classical descriptions of well-known conditions.

ARRESTING HAEMOPHILIC HAEMORRHAGE

For many years blood transfusion has been known to be valuable in the arrest of haemophilic haemorrhage. At first the benefit was attributed to the content of platelets but it was later shown that plasma free from factors I and II was as effective as whole blood.¹ During the last twelve years work has been carried on in the U.S.A. with the object of identifying and preparing for therapeutic use the anti-haemophilic substance or substances in plasma. Results have shown that the responsible factor resides in the globulin fraction of the plasma protein.

Minot and Taylor² have recently summarized this work. They describe and compare the results obtained from intravenous injection of Cohn's plasma Fraction I, I₁ from fibrinogen and prothrombin, with the effects of transfusion of blood or whole plasma: 400 mg. of Fraction I dissolved in isotonic saline produces roughly the same effect as 100 ml. of fresh blood or 80 ml. plasma. The accelerating effect on coagulation may last for 48 hours and enable operations such as dental extractions to be carried out with comparative safety. The results are, however, variable; the effective dosage differs from patient to patient, some who react to crude plasma will not respond to the separated fraction. Minot and Taylor claim that the reactions are caused and that injections may be repeated given without a refractory state developing. There is, however, some doubt on this latter point. In a recent report Craddock and Lawrence³ describe the development in patients with haemophilia of a circulating anticoagulant capable of slowing the coagulation of normal blood *in vitro*. Both patients became refractory to treatment with either fresh whole blood, plasma, or Cohn's Fraction I; in fact, the anticoagulant seemed to develop after repeated transfusions or injections of anti-haemophilic globulin. These observations may not be so exceptional for it has long been recognized that in some haemophiliacs the benefit of repeated transfusions becomes less as time goes on. Craddock and Lawrence's report is not encouraging from the point of view of the future prevention of haemophilic haemorrhage by injection of preparations of human plasma.

Very powerful haemostatics for local application have recently been developed in the U.S.A. Preparations of powdered human and animal thrombin, free of fibrinogen on which to act can coagulate blood in a few seconds, and may be applied directly to the bleeding site. This is, however, only a side issue; the fundamental problem of correcting the abnormality in the plasma of haemophiliacs has not yet been solved. Great progress has been made, but there is still a long way to go.

THE ADVANTAGES OF IMPURE PENICILLIN

It has been suspected for some time that the imperfectly purified penicillin of earlier days was more effective than the refined present-day product. This suspicion first arose in connexion with the treatment of syphilis, the earliest results of which were obtained with crude material in doses quite inadequate by present standards: they were nevertheless better, at least when allowance is made for altered dosage, than those obtained since. Recent investigations now tend to confirm the suspicion. In connexion with syphilis itself Dunham and Rake¹ first noted more than two years ago that crystalline penicillin G had no effect *in vitro* on the motility of *T. pallidum*, whereas impure penicillin reduced it. Rake, Dunham and Donovan² have now gone further and shown that certain samples of pure commercial penicillin were decidedly more active than pure penicillin G (the most active of the pure types) in the treatment of syphilis in the rabbit. Another observation pointing in the same direction is that of Groupe and Rake,³ who found that the action of commercial penicillin on the viruses of canary pox, fowl pox, and vaccinia was entirely due to impurities; this activity persisted after the penicillin itself had been destroyed with penicillinase, and pure penicillin had no effect.

The most exhaustive study so far on this perplexing problem is that of Hobby, Lenert, and Hyman.⁴ They began by comparing the effect of penicillins of various degrees of impurity with that of pure penicillins X, Y, and Z in mice. Having established that, unit for unit, the impure materials were more effective, they worked thenceforth with one of these which had an activity of only 54 units per mg. and with pure penicillin G. The relative therapeutic efficacy of these two materials may be expressed by saying that 100 units of the former had the same effect as 250 to 300 units of the latter. They showed that when the impure material had been treated with penicillinase a small quantity of it would enhance the activity of pure penicillin. The degradation products of the impure material must be due to an unknown substance other than penicillin derivatives. This substance also enhanced the activity of other penicillins than G. An admixture of K enhanced the activity of G to a greater extent than would be expected on a unit basis. This study, in which 25,000 mice were used, deals also with other aspects of the subject, but its main interest is in showing conclusively that in the purification of penicillin something unknown and valuable is lost.

When the full therapeutic possibilities of penicillin were first envisaged it was expected that deliberate modifications of its molecule might widen the sphere of its usefulness. This prediction has not yet been fulfilled, and in the meantime the chemistry of natural penicillins has proved unexpectedly complex. According to Winsten and Spark⁵ the number of these may be as great as eleven. But the added complication of an impurity or impurities of unknown nature enhancing therapeutic effect is still more baffling. Until these substances can be identified it might well be worth while to revert to older methods of manufacture, and so return to the cruder product which we have unjustifiably despised in recent times. Highly refined penicillin is essential for intrathecal and intraocular use, minor disadvantages; it is more painful, more apt to cause local inflammatory changes, and perhaps more often responsible for sensitization phenomena. At least we now

have an explanation why the standard dose of 100,000 units a day which was used for almost all purposes in early therapeutic studies was apparently as effective as the larger doses used to-day. Whether to change manufacturing policy in view of these discoveries must depend in part on the supply position: the present shortage would appear to favour the change and could doubtless be relieved by it. We have no information that such a step is contemplated, but it appears to deserve serious consideration.

DIAGNOSIS OF ADRENAL TUMOURS

Two fatal cases of adrenal tumour are described in this week's *Journal*, one of a 14-year-old girl with virilism and hypoglycaemia reported by Mr. L. R. Broster and Dr. J. Patterson, and the other of a 40-year-old policeman with gynaecomastia reported by Drs. C. N. Armstrong and J. Simpson. The correct diagnosis was soon made in the first case because of virilism and a huge output of urinary neutral 17-ketosteroids (the patient excreted almost 2 g. in a day), but despite this she died within 10 days of admission to hospital owing to hypoglycaemia which was so severe that she alternated between fits and coma and could not be brought to operation. In the second case a full investigation of the complaints of abdominal pain and night sweats did not reveal the cause of the symptoms, and it was only when the patient returned to hospital three months later that an adrenal tumour was diagnosed. The daily output of neutral 17-ketosteroids at this time was 34 mg., but later this rose to 104 mg. when the inoperable tumour had grown and secondaries had developed in lungs and liver. In spite of this it seems probable that the tumour was chiefly secreting oestrogen, since there was an associated gynaecomastia. Seven other similar cases to this have been reported in the literature, and in the two in which oestrogen output was determined it was abnormally high. These two cases illustrate the value and limitations of 17-ketosteroid estimations in the diagnosis of adrenal carcinoma. A rise in output is suspicious, but the extent of the rise does not mirror the degree of overactivity of the gland, nor does it coincide with the extent of virilism in women, for the girl with the huge output was less severely affected than girls of similar age with adrenal hyperplasia and outputs only 5-10% as great. This is where Patterson's colour test for dehydroisoandrosterone may be valuable. It is reported that this compound or closely related ones are present as a higher proportion of the ketosteroid output in cases of adrenal tumour than in cases of adrenal hyperplasia. So far Patterson¹ has applied the test to the neutral 17-ketosteroids from the urine of nine cases—three of adrenal tumour and six of adrenal hyperplasia. Positive results were obtained only in the former. The test has not yet had a severe trial since the output of neutral 17-ketosteroids per day in the two groups were widely separated—24-81 mg. in the hyperplasia group and 215-1,980 mg. in the tumour group. A crucial test of the value of the colour reaction will have to be made on a case such as that reported by Armstrong and Simpson, in which the output was relatively low. An interesting point is made by Broster and Patterson, who remark that their patient had a solitary adrenal gland is associated with isosexual precocity. This agrees with the finding of one normal adrenal in the policeman. The endocrine changes might be *run ad infinitum* to account for this and for the hypoglycaemia in the young girl.

THE LOYAL ADDRESS OF THE BRITISH MEDICAL ASSOCIATION

We print below the loyal address of the British Medical Association to His Majesty the King on the occasion of the twenty-fifth anniversary of Their Majesties' marriage.

To The King's Most Excellent Majesty:

The Humble Address of the President and Members of the British Medical Association.

May It Please Your Majesty,

We, Your Majesty's dutiful and loyal subjects, the members of the British Medical Association distributed throughout Your Majesty's Commonwealth and Empire, humbly offer to Your Majesty, and to Her Most Gracious Majesty the Queen, congratulations on the twenty-fifth anniversary of Your Majesties' marriage.

We beg leave on this auspicious occasion to express to Your Majesty our unfailing fidelity to Your Majesty's Throne and Person. We recall with deep gratitude Your Majesty's constant devotion to the well-being of Your Majesty's subjects throughout the past years of grave national privation and peril, and it is our fervent hope that Your Majesty's benevolent reign may long continue in a future blessed with prosperity and peace.

Signed on behalf of the British Medical Association:

HUGH LETT, *President.*

H. GUY DAIN, *Chairman of Council.*

J. B. MILLER, *Chairman of Representative Body.*

JOHN W. BONE, *Treasurer.*

NATIONAL HEALTH SERVICE TRIBUNAL THE LEGAL ASPECTS

BY

J. ARTHUR GORSKY, L.M.S.S.A.
Barrister-at-Law

The claim made by Lord Horder at the Special Representative Meeting on Wednesday, March 17, that the doctors were fighting for liberty is consistent with the recent statement of the National Executive Committee of the Labour Party that "... democracy cannot live without freedom of speech, press, and organization; without the right to protection against arbitrary arrest, the right of appeal to a non-political judiciary." This declaration of democratic principles, to which we as a free profession whole-heartedly subscribe, sounds a note of warning that these principles are our only safeguard against delegated legislation.

The growth of Administrative Law is a fundamental change in Constitutional Law, which developing slowly has now gathered momentum and threatens our liberties. The tendency of modern legislation is for Parliament to state the broad principles of its policy in an Act which empowers the Minister of State to delegate the duty of developing the details by Regulations and Orders to his executive administrative officers, who may be invested with delegated adjudicatory powers against which in some cases there is no right of appeal.

It is our duty as a medical community to be on guard against the uncontrolled growth of Administrative Law so far as it affects us in the provisions of the National Health Service Act and the subsequent Regulations and Orders that the Minister of Health, or those purporting to act for the Minister, may make by virtue of the very wide powers given to him in Clause 75.

Two evil tendencies have developed as a result of this system of delegated legislation. They were emphasized by Lord

Reading in the House of Lords when he introduced the Labour Party's Bill for the "Preservation of the Rights of the Subject."

"... the growing usurpation by the Executive of the power of Parliament, and the increasing exclusion of the courts of Law from what is perhaps their supreme function—protecting the individual citizen against excessive and illegitimate encroachment on his rights and abuses of authority."—(*Hansard*, Vol. 147, No. 71, p. 764.)

The doctors demand the right of appeal to a non-political judiciary, and in my view we cannot subscribe to the opinion expressed by Mr. Bevan that to give the doctor his right of appeal to the High Court against his dismissal "would be a judicial sabotage of socialized services." (Parliamentary Debates: Standing Committee C, Wednesday, June 26, 1947.) There has been, in my opinion, a considerable amount of less thinking and confused writing on the contentious question of "right of appeal."

Inquiries by Government Departments

The disquieting element in Clause 42 is subsection 7 (b), which empowers the Minister to apply, with modifications, any of the provisions of Section 290 of the Local Government Act, 1931, which is designated "Power of Government Departments to Direct Inquiries." Two very important implications result from this power possessed by the Minister:

1. The Tribunal becomes a departmental inquiry and is therefore *not* an independent tribunal, in spite of the fact that the legal chairman is appointed by the Lord Chancellor.
2. As such it becomes an "administrative" and not a "judicial" body.

The distinguishing features of an "administrative" tribunal are that it is a law unto itself, and that it possesses a "pure," "absolute," "complete," or "unfettered" discretion. The extensive case law on the subject makes it quite clear that no right of appeal is granted in the Act the High Court cannot interfere with an administrative tribunal's exercise of the discretion given to it. Such a tribunal is master of its own procedure except where an Act specifies that the Minister shall make regulations prescribing such procedure.

The National Health Service Act, 1946, gives the Minister power under Clause 42 (7) (a) to make regulations for prescribing the procedure for the holding of inquiries by the Tribunal. It is noteworthy that all the Minister has ordained is contained in Regulation 35 in the National Health Service (Service Committees and Tribunal) Regulations, 1948, which states the proceedings shall be held *in camera* unless the respondent has applied for the inquiry to be held in public, but otherwise the procedure at the inquiry "shall be within the discretion of the Tribunal." The High Court can only interfere in a limited way if the decision of the Tribunal "is contrary to the manifest principles of justice."

Administrative Law

The vital point at issue is whether "administrative" tribunals do in fact administer justice. In my submission they do not function as judicial courts but base their decisions on policy and expediency and not on legal rights and liabilities. The exercise of their power rests not on law but on opinion. Their discretion refers to their powers of fact-finding which the High Court cannot override. They have far wider powers than judicial tribunals to decide for themselves what they will do, or whether they will do anything at all.

The High Court cannot impose its own standards of procedure or make such a tribunal conform to the rules of evidence which usually operate in the High Court. If there is an error or defect in jurisdiction, or a vital error in procedure which needs remedying, then the High Court can exercise its control in these very exceptional cases by means of its orders of certiorari, prohibition, or mandamus.

"Administrative" tribunals cannot be compelled to state a case to the High Court, and with few exceptions are not under any obligation to give reasons for their decisions. A doctor would be dismissed on a finding of facts (Regulation 42), and he would not have the power to ask for a case to be stated, nor could he compel the Tribunal to give any reasons for its decision. Dismissal on a legal point, which would be extremely rare, might conceivably give the dismissed doctor the right to

ask for a case to be stated by the Tribunal, but only where the legal point dictated the decision of the Tribunal. How will the doctor know that, if an "administrative" tribunal need not give any reasons for its decision? Therefore in my submission there can never be a case of unlawful dismissal if you cannot challenge the fact-finding decision of an "administrative" tribunal. The right of appeal to the Courts has been taken away from the doctor in spite of Mr. Bevan's assertion in the debate on Monday, Feb. 9, 1948 (*Hansard*, p. 43). Therefore the only appeal of the doctor will be to the House of Lords made it clear what this would mean. "A doctor would be condemned to professional death for something much less than misconduct on a report of an inspector of the Ministry which would not necessarily be read by a busy Minister." The matter can be argued in another way. Unlawful dismissal implies an injury to a "right"—the right of a doctor to practise under the National Health Service Act. "Jordan" has discussed this.

"But apart from a right to have prescribed procedure followed, no one can have any rights before a tribunal acting 'administratively'; rights are outside its province; no one has a right to a favourable decision; and though incidentally the tribunal may consider points of law, such points, whatever view may be taken of them, can never dictate the decision that the tribunal must make. For the decision must be governed by policy and expediency; and though the state of the law may be a factor in policy and expediency, it can never be the governing factor; otherwise policy and expediency cease to have meaning and are only other names for justice. But the tribunal is not judicial, and so does not administer justice, it must suit itself as to how far it lets points of law enter into its policy. This is one very good reason why tribunals acting 'administratively' cannot state cases, except on points of jurisdiction or prescribed procedure. A stated case must raise a point of law that concludes the question whether the decision was right or wrong; whereas, whichever way the High Court rules on a point of substantive law, this ruling can never determine whether an 'administrative' order was right or wrong. Indeed such an order never is right or wrong, correct or incorrect."

There may be a regrettable mistake of law which the Court cannot question; but the Tribunal's mistake of law will not deprive the doctor of a legal right. It will be the "administrative" order which will deprive the doctor of his right to practise. As this order will never be "right or wrong, correct or incorrect" it follows that there never will be a legal injury to that right. And where there is no legal injury there cannot be a legal remedy.

Mr. Bevan in his speech on Feb. 9 postulated some curious doctrines. They accentuate the dangers of Ministers' powers in delegated legislation which, like Clause 35, the iniquitous penal clause, are insidiously altering the Constitutional Law of this country. He asserted that to allow the doctor the right of appeal that he had been wrongfully dismissed in the terms of his contract would completely revolutionize the relationship of the judiciary to the legislature. As a rejoinder to that assumption I quote Prof. Laski: "It is difficult to overestimate the significance of the judiciary in the modern State. The work of the Executive has become so vast, the powers delegated to it by the legislature are so wide, that the judges are, perhaps more than at any previous time, the real safeguard of personal liberty. It is only necessary to recall cases like *Coppage v. Kansas*, or *R. v. Halliday*, to realize how nearly judicial activity goes to the very heart of freedom." The Minister of Health agrees that "the courts are competent to judge the law and to construe the statutes. . . ." Since when have the judges not been competent to evaluate facts and to give decisions on matters of fact? By virtue of education, training, experience, high mental calibre, and complete impartiality they are more competent to decide these matters than a Minister. It is not suggested that such a tribunal will not be impartial, but only one member of the tribunal will not be a lawyer and he may be overruled by two non-legal members.

Another conception which should be refuted is that the relationship between the Minister and the doctors is that of employer and employees. The Law of Master and Servant does not apply. A clerk is a servant; an opera singer under contract is not. The contract between the doctor and the local Executive Council acting as agent of the Minister is in my opinion

in the nature of a partnership or quasi-partnership agreement. The limitations of space do not permit me to amplify this point.

Any Other Person

There are two other disturbing features of Clause 42 which must be stressed. The Tribunal must inquire into representations made by an Executive Council that the continued inclusion of a general medical practitioner in the list of those undertaking to provide general medical services would be prejudicial to the Service. But it may inquire in like manner if representations are made by any other person. Although the wording of the Clause is only permissive in this latter case, it is pernicious because it enables any other person to by-pass the Executive Council and go direct to the Tribunal. It is of paramount importance to remember that the Minister of National Insurance Service Act as well as his own National Insurance Act, 1946, and by-pass the local Executive Council. In this connexion would draw attention to Regulation 10 (d) (i) of the preliminary draft of the National Insurance (Unemployment and Sickness Benefit) Regulations, 1948.

By virtue of the power under (7) (b) of Clause 42 the Minister has applied subsection 5 of Section 290 of the Local Government Act, 1933, in Regulation 37 relating to the Tribunal. This gives the Tribunal power to make orders as to costs which may be made a rule of the High Court. It is not clear whether costs under this subsection may be taxed under rule 15, Order 65, Rules of the Supreme Court, nor is there any mention of a right of appeal against this award of costs. Not only is a doctor liable to professional death but he may be mulcted in onerous costs as an additional penalty.

We are enjoined to enter the Service and improve it by experience and practice. To that I would reply *Quod ab initio non valet, in tratu temporis non convalescit*. That which is bad from the beginning does not improve by length of time. Dr. William A. Robson, Professor of Administrative Law, London University, has drawn attention to "the lack of principle which has been manifested by Parliament in naming the appellate body to which a citizen must go for redress. There is no clear distinction drawn between the class of cases which are to be decided by the courts of law and that which goes for determination to one of the central departments of Government. . . . Much could be done to make the ordinary business of litigation more rapid and less expensive to the parties than at present, and it is preferable that the courts of law should be improved in these respects than that judicial functions should be conferred on administrative bodies merely in order to attain those ends."

Finally I refer to Mr. Bevan's opening words in the debate on Feb. 9, and submit for the reasons I have expressed in this contribution that the conditions under which the Minister of Health has invited the medical profession to participate in the National Health Service Act are not fully in accord with our professional freedom and dignity.

A new film-strip which has been issued recently by the Medical Unit of the Unicorn Head Film Strip Library has been prepared with the technical assistance of Dr. R. C. MacKeith and Mr. J. M. Watson. The strip, which has eighteen frames, deals with the diagnosis of threadworm infestation, and shows particularly the collection of ova by the glass pestle method and by use of adhesive "cellophane" tape. This film-strip is concerned only with diagnosis, and further information about it may be obtained from the Technical Director of the Unit at 177, The Vale, Acton London, W3.

BRITISH MEDICAL LIBRARIES

BY

W. R. Le FANU, M.A.

Librarian, Royal College of Surgeons of England

London is better provided with medical libraries than any other city in the world. There are great libraries in Edinburgh and Dublin; Manchester has an excellent medical library, and most of the other university towns are well provided for also. How far do these large collections meet the profession's demand for literature? Lord Justice Asquith (1944) wrote in *The Times* a few years ago that "County Court judges work under grave handicaps as regards law libraries." Is the provincial physician or surgeon in a like predicament? Are the existing libraries sufficiently complete and accessible, and is the service which they offer fully known to the profession at large?

The newest work in every branch of science and medicine appears first in the pages of periodicals, but subscription to more than a few of the 2,000 medical periodicals now published each year is too expensive for the private pocket, and to keep back-numbers even of those few is too space-consuming in the private house or flat. The collection and provision of periodicals has thus become the chief preoccupation of active libraries, and on libraries the reader relies who wishes to follow all the latest work and to look back over the sequence of previous work in his field of inquiry.

Two great London libraries, those of the Royal Society of Medicine and the British Medical Association, provide for their Fellows and Members throughout the country a very complete reference service, lending books or sending photographic copies when a particular book cannot reasonably be allowed out of the library, besides supplying bibliographies, translations, etc. In fairness to their subscribing membership neither of these libraries can extend its service to non-subscribers, though the Royal Society of Medicine generously allows visitors the use of its books at the library. Each of these libraries aims to amass a full collection of medical periodicals of the entire world. The Royal Society of Medicine, which already owns an unrivalled store of older medical periodicals, stated before the recent war its intention "to collect all representative medical journals from every country." Recently the British Medical Association has begun to collect all available medical periodicals from all over the world. Gathered in the first place for the work of the Association's abstracting service, they will be permanently available in the library. As these attempts at comprehensiveness reach towards their completion London will become increasingly the outstanding repository of medical literature, for it must be remembered that the national library at the British Museum also has a very wide collection of medical periodicals in many languages. The task before the authorities of other medical libraries will therefore tend to become that of taking special fields for intensive cultivation and serving a clientele specialized by its locality or interest or status, which will rely for wider study on access to the general libraries.

Outside London the great university libraries, notably those of Oxford and Cambridge, Manchester, Bristol, Edinburgh, Glasgow, and Dublin, are richly stocked. With these must be counted the fine libraries of the Royal Colleges of Physicians of Edinburgh and of Ireland and the Liverpool Medical Institution. All these libraries cater principally for the clinical specialist. They are supplemented for the general practitioner by a large number of smaller libraries, chiefly those of local medical societies, which have their prototype in the Medical Society of London. The libraries in this class are for the most part maintained for the use of each society's own members, though in some cases the library's facilities are extended to all practitioners in the district. The lesser libraries cannot offer their readers more than a simple lending service of current books, for which in many cases they rely, as do many individual doctors and students, on the subscription lending library which has been maintained for a century by Messrs. H. K. Lewis, the medical booksellers and publishers. The reference collections of these local libraries are of very varying value, and in many cases inadequately administered. Use-

ful as their service is, an insurmountable weakness lies in their not being able to offer their readers ready access to a wide range of current periodicals or of older work.

Facilities for Research Workers

This weakness is particularly felt by the research worker. For him the specialist libraries are peculiarly valuable, though of course he must rely also on the general libraries already named. At the universities, notably at Oxford, Cambridge, and Dublin, each research department maintains a small library of its own supplementing the main university collections, but in almost every case these are purely for private access by the research staff of the particular department. Similar private staff libraries are maintained at research institutions such as the Lister Institute and the Imperial Cancer Research Fund, and at the research departments of hospitals and of commercial pharmaceutical manufacturers and the like.

The most efficient research library and one of wide professional usefulness is that of the Medical Research Council at the National Institute for Medical Research at Hampstead which provides library service for all the centres of research of varying size and scope promoted by the Council up and down the country. This Government-supported library is most liberal in extending its facilities to other medical libraries by inter-library lending, thus making its resources available far beyond its immediate duty and benefiting in return by the reciprocal facilities earned. The large library at the Ministry of Health is a private staff library similar to those named above. The Medical Research Council of Ireland does not itself maintain a library, but has promoted the work and liaison of existing Irish medical libraries.

Two large special libraries in London are particularly valuable to the research worker—those of the London School of Hygiene and Tropical Medicine and the Royal College of Surgeons of England. Though both are essentially the private libraries of their institutions, whose members, staff, and students have first claim upon their resources and service, each has always been administered in a liberal spirit. The library of the Royal College of Surgeons is among the larger medical libraries in the country, rich in long series of periodicals. These are confined, with a somewhat wide interpretation, to the literature of surgery, its specialities, and the sciences ancillary to surgery. In particular the library is strong in the literature of anatomy and physiology. It is thus peculiarly well fitted to cater for postgraduate students of surgical specialities and for advanced workers in the basic sciences. Its collection of nineteenth-century books is probably, within its own field, second only to those included in the general collection of the Royal Society of Medicine; in modern books it is more strictly specialized. The library of the London School of Hygiene and Tropical Medicine has from its inception 25 years ago been closely specialized in its two chosen fields, in which it has built up first-class collections. It has always been liberal in lending books, both directly to other libraries and through the general system of inter-library loans organized by the National Central Library. The Liverpool School of Tropical Medicine also has an excellent specialized library.

The restriction of certain libraries to intensive collection of a chosen subject opens the way for the possible development of a system of mutually complementary, while fully independent, libraries. The potentialities of such a policy are of great interest among American library authorities at present, more especially with regard to the acquisition of foreign books. At home there is more concern among medical librarians to agree upon delimitation of fields before planning acquisition. If it could be agreed that everything available in a particular subject would be the special care of a certain library or libraries, the organization of information service for the whole cadre of research workers would be simplified. The time has gone by when the research worker was ploughing a lonely furrow and relying on the library resources of the institution to which he happened to have right of access. The delimitation of libraries lags behind, but without in any way giving up their individuality they are moving towards a generalization of service. A corollary of any such agreement to specialization would be the transference to each specialist library of the material in its chosen subject held by libraries now conducting general

activity to other interests. A step in this direction has lately been taken by the transference from the Royal College of Surgeons of much of its holdings in public health, both series of official reports and individual books, to the London School of Hygiene. The success of this policy depends on the willingness of libraries to lend their books to other libraries and also to admit readers from outside their own membership, for it is often quicker, at least in London, to get the reader to the book than the book to the reader. These facilities, which are of course only possible for non-subscribing libraries, are now very general practice.

There are in active existence a number of important specialized libraries of this nature, notably those of the societies and institutions on the borders of medicine, such as the Pharmaceutical Society, the Royal College of Veterinary Surgeons, and the Royal Sanitary Institute. These are already the natural resource of the worker in each particular field. But equally there are a number of unfilled gaps. There is no single library, for instance, to which an inquirer for medico-legal literature can be confidently recommended. No doubt the general medical libraries, the university libraries, and the great law libraries could between them supply all reasonable requests in this subject, but the individual inquirer would have to search those sources for himself.

Collaboration between Libraries

This is the point at which there is most need for concerted action by libraries. There is at present no means of knowing, except by direct asking at each individual address, what are the resources of the profession's libraries except in periodicals. The principal medical libraries are included in the two available union-catalogues, which record the holdings of periodicals in the country's libraries; both of them are now considerably out of date, however. The *World List of Scientific Periodicals*, 1934, includes the major institutional libraries, while the *Union Catalogue of Periodicals in University Libraries*, 1937, includes the libraries of medical schools affiliated to universities; but these two lists together are not exhaustive. A *List of Medical Libraries and Information Bureaux in the British Isles J. Docum.*, 1946, 2, 119) published by Aslib (the Association of Special Libraries) shows that there are some 150 medical libraries of varying size and type in existence here. Several projects for collaboration among them are taking shape at present. Quite recently mutual action by the librarians of five large medical libraries in London, helped by a generous grant from the Medical Research Council, has produced a card-catalogue of their holdings of current periodicals. Copies of this catalogue have been deposited at each of the libraries which co-operated in its completion—namely, the British Medical Association, London School of Hygiene, Medical Research Council, Royal College of Surgeons, and University College, London (Thane Library of medical sciences), and at other centres. It is intended to keep this catalogue regularly up to date.

The Central Medical Library Bureau, established by the Rockefeller Foundation at the Royal Society of Medicine at the end of the recent war, is still preoccupied with its first charge of helping war-scarred medical libraries on the Continent. It is at the same time compiling a union list of current periodicals in the major medical libraries of the British Isles, and its facilities for the supply of microfilm copies of medical literature that cannot be borrowed, traceable by this new union-catalogue, will simplify the present haphazard methods of inter-library lending, which have, however, worked well to the mutual advantage of many libraries and their readers through many years. The Central Bureau has generously placed modern microfilm reading-machines in the principal medical libraries of the country. Thanks to the existence of American and French union-catalogues and of excellent free microfilm services in Washington (Army Medical Library) and Paris (Faculté de Médecine and Pasteur Institute) it is already easy for any medical library to obtain from those centres copies of articles not possessed anywhere in Britain.

Even more promising but still awaiting funds for their prosecution are two schemes planned in some detail through the Library Association, the professional body of librarians. The

University and Research Section of the Library Association has worked out a scheme for surveying and making known, and thereby more readily accessible, the resources of the research libraries of the country in every subject including medicine. The second scheme is confined to medical collections. Last autumn medical librarians formed themselves into an organized group within the Library Association, which will, it is hoped, soon become a substantive section of the Association. Such an association of medical librarians was proposed by Sir William Osler at the Annual Meeting of the British Medical Association so long ago as 1909. A similar body—the Medical Library Association—had then been active in America for a decade and is to celebrate its fiftieth anniversary in May of this year. The Medical Library Association, which is international in scope and to which several British libraries belong, has done much to promote the activity and prosperity of medical libraries by its conferences and publications. Its service for the exchange of duplicate material is efficient and highly practical in placing books where they are needed. The newly formed British group of medical libraries has in preparation, but also awaiting funds for its completion, a union-catalogue of all periodicals in medical libraries throughout the British Isles. The group has already established a pool for interchange of duplicates, which is being administered by the Wellcome Historical Medical Library.

The chief demand of clinicians and students is for current literature, but the research worker ignores the work of his predecessors at the risk of overlooking undeveloped hints, of losing perspective in his attack on new problems, or even of wasting effort over work already recorded. François Magendie (1827) remarked long ago that, in turning up the authorities after making some fresh physiological observation, he had often found his complete discovery in Haller's *Physiology*, published more than a generation earlier. "I was much put out," he wrote, "and often cursed that wretched book in which I found everything, but I was consoled to realize that, since others had made discoveries before me, by persisting at work I could still find some unobserved facts."

Historical medical literature is not a mere symbol of prestige or even of proud tradition for the libraries who own it: it is the only record of previous progress. As Mr. Churchill (1944) reminded the Royal College of Physicians, "The longer you can look back the further you can look forward." The wealth of historical literature in this country is immense. The British Museum, William Hunter's library at Glasgow, the Royal College of Physicians of London, and the Wellcome Historical Medical Library are only the outstanding collections in a series probably without match in any other country. The resources of these collections, scattered over many medical libraries, both in rare early books and in the literature of the last two centuries—the period of Hunter, Jenner, Lister, and our immediate predecessors—are comparatively unexplored. Certainly they have not been cared for and developed as have the corresponding collections in America. Their value as essential tools in the humanist approach to medicine is now better realized and more attention is being paid to their upkeep and development. The possibility of co-operative cataloguing of this material is now being mooted.

Co-operative attack on the various projects outlined above ought to promote a spirit of friendly rivalry among libraries to achieve their common aim, previously pursued in too isolated units, which is to provide their readers with access to a full range of medical literature in the simplest and quickest way. One class of readers which is not adequately catered for is that of medical students. Each medical school has its library, but their book stock and administration is of varying quality, while there is in London an overall shortage of reading-room space for undergraduates. The medical schools in London are all affiliated to the University, but there is no correlation of their library services. Library provision for the teaching and research staffs of hospitals is similarly uneven. Many of the older hospitals have fine historical libraries lacking adequate care or staff; some of the newer hospitals are providing (Avery Jones, 1948) up-to-date library service for their whole-time specialists. In two or three provincial centres, notably at Manchester, hospital, medical-school, and medical-society

libraries have been combined, with marked increase of efficiency and service to the readers drawn from each group. Over the country as a whole, however, the need is not for unification but for development of individual units to the standard set by the best, through correlation of activities.

INQUIRY INTO BOOK SHORTAGE

Though the date when printing with movable types is not known exactly, it is thought to have been just about 500 years ago—1448. The extraordinary increase in man's knowledge of his environment that has characterized the last five centuries has depended largely on the swift interchange of ideas, especially by means of printed matter; and the demand for serious books, particularly works of a scientific or technical nature, is probably greater to-day than it ever has been. Unfortunately, it cannot be satisfied in this country.

We have heard complaints from medical students and practitioners for some time that they cannot obtain enough books. In order to discover if there is indeed a shortage of medical books—"medical" implying all aspects of the science and art of medicine—we wrote to most of the leading publishers and booksellers who specialize in these books and to the librarians in charge of a number of medical libraries. We asked them certain questions; there follows a report on their replies.

Books Most in Demand

In order to find out which particular books are most required by practitioners and students our first question to librarians and booksellers asked them to name the 10 medical books most in demand. It would be invidious to publish their selection of these books, but we have amalgamated the 24 lists that we received and added up the choices for each book. Ten books were named in 6 or more replies, one book being distinguished by as many as 17 votes. These 10 books were all standard textbooks and comprised 2 textbooks of medicine, 2 of surgery, 2 of pathology, 2 of applied physiology, and 2 of anatomy.

Is the Demand Met?

Our next question to librarians and booksellers was sent also to publishers: we asked whether they could meet the demand for British medical books. Of the 20 librarians who replied none answered unequivocally that they could do so, though one said that he could supply what was wanted except for books out of print and those—a few cases—out of stock, and one that the Copyright Act of 1911 ensured his receiving one copy of all books published. Thirteen librarians said that in general they could meet the demand, with various qualifications. Some order books before they are published, because they find that books run out of print soon after publication. They are therefore unable to assess the quality of a book before ordering it. Further, if a book should prove to be popular, it is usually impossible to obtain more copies, and the demand for it cannot be satisfied. Some libraries receive preferential treatment from local booksellers, enabling them to obtain at least one copy of a new book or new edition, but they may find that one copy is insufficient to meet the demand. Most remark on the long time that elapses between ordering a book and receiving it, 6 to 12 months being mentioned and even longer in a few cases, a circumstance particularly inconvenient to a small library that does not have several of the previous editions to lend. Only one librarian said that the funds at his disposal are the limiting factor rather than the book shortage. Four librarians replied that they are unable to meet the demand because a sufficient number of books are not available. The question did not apply to one librarian, but he makes the interesting point that, owing to the shortage of British books, students are using a number of American textbooks that are unsuitable for their particular course of study.

All the 6 booksellers who answered this question said that it was impossible to meet the demand or find it extremely difficult to do so.

cult to do so, the chief reason being that their waiting-lists for a particular book, especially the more popular, normally contain more names than copies of books they receive. Reprints or new editions of standard works often take as long as two years after issue of the previous edition to appear in the bookshops, with the result that some students may have to go through the whole of a course of study without being able to obtain a requisite textbook. One of the publishers mentions in this connexion that there have been times recently when no standard work on either anatomy or physiology was available. Of the 9 publishers who answered this question 7 said that they cannot meet the demand, or cannot do so in most cases, and 2 said that they can "after delays" or "only with very great difficulty." One comments that books required by only a few workers have to give place to standard textbooks, so that books on specialized subjects are unlikely to be reprinted when they ought to be. Another points out that the increasing specialization of medicine necessitates more books being published than before the war. He adds that the demand both at home and abroad is greater than formerly, and that the difficulty in obtaining books from America enhances the demand for similar British works.

We asked booksellers and librarians what classes of books were most difficult to provide—such as standard works on medicine and surgery, students' textbooks, research monographs etc. As might be expected from the lists they sent us of these books most in demand, the majority replied that their main problem is to supply sufficient students' textbooks and standard works on medicine and surgery. Two librarians find that monographs are the hardest to obtain. One bookseller comments that the supply fluctuates between different groups of books and mentions in particular that agricultural students are this year probably worse off than medical students. One librarian states merely that it is the more popular books that are difficult to get.

Causes and Extent of Shortage

The paper available for printing books is at present controlled by a quota. The basic amount is 60% of the previous quantity, and for educational (including medical) books and/or export a further 20% is allowed. There is also a booksellers' reserve, which provides paper additional to the quota for reprinting books that in the public interest should be kept in print. In addition there is an export pool to meet *bona fide* export orders.

In order to gain some idea of the causes and extent of the shortage we asked publishers, first, what the main causes are, and, secondly, the time compared with 1938 that elapses between acceptance of a manuscript and publication of the book. Of the 9 publishers who answered the first of these questions 4 stressed the lack of paper as the main important limitation. One of these added that difficulties over binding the books also caused delay, and another mentioned shortage of labour, especially in the binding industry. One publisher said that the main cause is the shortage of labour and machinery and 2 that it is delay in binding. Two find that all these factors impede them. One of the publishers who finds that binding is the main difficulty drew attention to the grave shortage of female labour; since the war, for various reasons, women have tended to remain at home who would before have gone out to work. The cotton required is also in short supply. It would be impossible to bind large books in paper covers and would have to come from the U.S.A. The materials and skilled labour required for the illustrations that must adorn many medical books are also scarce.

Eight of the 9 publishers find that it takes two or three times as long to produce a book now as it did in 1938—for example, nine months instead of three, two years instead of nine months. The one exception says that there is not much in it for him that he can plan ahead.

Fate of Manuscripts

Arising from the problem of having to allot the necessary paper ration to produce new books, new editions, and reprints is whether publishers must reject manuscripts that they cannot publish if they had sufficient paper. We put this question to them, and of the 9 who replied to it one said that he does not

Ribena therapy in skin conditions

That vitamin C has some beneficial effect on the health of the skin appears certain from the good results obtained in various skin disorders. Cases of acne rosacea, for example, have been reported to clear up following a course of 'Ribena' Blackcurrant Syrup. In allergic skin manifestations a dietary of green salad, supplemented with 'Ribena,' often proves effective. Clinical tests have indicated that Ribena has been of some value even in psoriasis, perhaps because of its content of vitamin P.

Ribena Blackcurrant Syrup has a high degree of acceptability and is well tolerated even in cases where the condition is complicated by digestive disorder. The vitamin C content of Ribena is standardised at 20 mg. per fluid ounce, with which are associated other factors of the natural product whose precise functions have not yet been clearly established.

Dietary Deficiencies

Although there seems to be no evidence of severe malnutrition in this country at the present time, there are, in individual cases, manifestations such as lack of concentration, lassitude, chronic fatigue and nervous disorders, which appear to be caused by inadequate diets. Some of these symptoms may be signs of a deficiency of the B vitamins.

Marmite is a yeast extract containing naturally-occurring riboflavin (1.5 mg. per oz.) and niacin (16.5 mg. per oz.) as well as other factors of the B group derived from yeast; these include pyridoxin, pantothenic acid, choline, biotin and folic acid.

The dietetic value of Marmite has long been recognised; it is prescribed extensively as a prophylactic measure in combating malnutrition.

PHENOXYETOL

P.E.G.

THE ANTI-PSYOCYANEA COMPOUND

HERE is an important new bactericide and antiseptic. Phenoxyetol (Nipa) is B-phenoxyethyl-alcohol, specially purified and standardised, for use in medical treatment and for pharmaceutical preparations.

Phenoxyetol is effective against certain gram-negative organisms, including *Ps. pyocyanea*. It is used by local application in the treatment of infected wounds... abscesses... indolent ulcers... associated with *Ps. pyocyanea*. It should not be used for parenteral injections.

Phenoxyetol is very effective in pyocyanea infections of burns or superficial wounds. It is especially useful in the preparations of surfaces for skin grafting associated with *Ps. pyocyanea*, and may also be used together with Penicillin in solutions and creams.

the threefold tonic—for children everywhere

The problem of the run down, debilitated child is shared by medical men throughout the world . . . and the universal answer is a tonic, at once formative, restorative and protective.

Syrup Minadex is such a tonic, combining in its formula three distinct therapeutic groups. One group consists of iron, copper and manganese, included for their haemopoietic properties. The second comprises the glycerophosphates of calcium, sodium and potassium—traditional nerve restoratives. And the third group—vitamins A and D—furnishes the nutritional 'background' to promote the growth of healthy tissues and, in convalescence, to speed the return to full health. These ingredients are combined in a delicious orange-flavoured syrup, making Minadex acceptable to even the most fastidious palate in the warmest climate.

Vitamin Therapy *-its uses and limitations*

SEBORRHOEIC DERMATITIS

especially when occurring near the naso-labial folds and associated with cracking of the lips and conjunctivitis, may be an indication of mild ariboflavinosis. A mild deficiency of riboflavin is not uncommon in this country at the present time when foods containing good supplies of this factor are scarce. The vitamin is available in tablet form. Since however these deficiency signs frequently accompany indications of other B-complex deficiencies, it may better be given with other factors in a combined preparation.

DERIPHYLLIN

THEOPHYLLIN and DI-ETHANOLAMINE

Indicated in

**Cardiac Decompensation, Oedema,
Angina Pectoris and Cardiac Asthma**

Deriphyllin has a regulating action on water metabolism and influences the cardiac mechanism. By dilating coronary vessels and relieving any coronary spasm it may be present an improved flow of blood through the heart-muscle is secured.

Deriphyllin is exceedingly well tolerated and may be given for a long time (chronic cardiac decompensation) without reaction occurring. Effect does not decrease after prolonged administration. Can be usefully combined with the organic mercurial diuretics. Not contra-indicated in renal disease.

Available in liquid form for oral use,
ampoules and suppositories.

Deriphyllin-Strophanthin is indicated for all cases of heart failure.

Available in the form of ampoules and suppositories.

to do so. Five stated that they must refuse some manuscripts, one of these mentioning that this selection particularly "doubtful" manuscripts likely to have a limited sale, another saying that he has to refuse manuscripts because they would be out of date by the time they could be published. The publisher does not reject any work considered suitable for publication but solves the problem by reducing the size of editions. Five said that he has not had to reject any "major" works, one that the shortage of compositors causes long delay in getting a new book set up in type, whereas reprints do not suffer so much.

Books from Abroad

Generally, we put two questions to booksellers and librarians: the supply of foreign medical books, asking (a) whether they can obtain sufficient to meet the demand, and (b), if not, whether that is due to shortages abroad or restrictions at home. Of 19 librarians and 6 booksellers who answered the question, 6 librarians said that they have little difficulty in obtaining sufficient foreign books, or that they receive what they require, though the book may be long in coming, or that they receive only a few unimportant books. The remaining librarians all experience greater difficulty in varying degrees. The booksellers agree that they cannot obtain enough foreign books.

Generally, American books seem to be the most difficult to obtain, though some replies stress German books. The main reason given for the shortage is restrictions imposed on their export into this country. In addition the demand is greater than it was before the war, partly because of the lack of British books, and partly, so one bookseller comments, because commercial firms are ordering many more. Some replies mentioned that the shortage is aggravated by there being insufficient paper for these books in the U.S.A.

In conclusion we acknowledge with thanks the time and care given by these publishers, booksellers, and librarians on answering another questionnaire.

DANISH MEDICAL ASSOCIATION NEW HEADQUARTERS

During the war and the occupation of Denmark by the Germans the Copenhagen headquarters of the Danish Medical Association were blown up; the destruction was so great that little of value remained apart from the building site. The plan of rebuilding on this site seemed almost prohibitive, but plans for rebuilding were still far from complete, when, at the beginning of this year, a valuable property elsewhere in Copenhagen came into the market. In February this property, a photograph of which is here reproduced, was bought by the Danish Medical Association for one and a half million Danish kroner. The Association will take possession on June 1, 1948.

THE PATIENT'S CONSENT

If a medical examination is made without consent it is a technical assault, possibly an aggravated or even an indecent assault, for which the practitioner may be prosecuted in a criminal court, or a trespass for which he may be sued in a civil court. In law, apart altogether from those cases in which medical examination is required in connexion with criminal or civil proceedings, consent is necessary for the examination of a patient in the ordinary course of practice. Where there is any possibility of doubt, consent should be obtained in writing, and in all cases in the presence of disinterested witnesses. An oral acknowledgment of consent is good in law, as indeed is implied consent arising out of the relationship of doctor and patient, but to free the practitioner's mind of anxiety a written statement should be obtained if possible.

The Medical Defence Union has prepared for its members an important memorandum designed to clarify and emphasize the legal position. To obtain consent the practitioner must explain carefully to the patient the need for an examination to arrive at a diagnosis or decide on a line of treatment. No sweeping promises should be made, and any risks in the proposed procedure should not be minimized. If for psychological or other reasons it is undesirable to discuss these matters with a particular patient the information may be placed before some near relative who—preferably still in conjunction with the patient—may give the necessary sanction. The form of consent should be unequivocal, and should be wide enough to enable the practitioner to adopt any further or alternative procedure which may be found necessary. It should also include consent to the administration of an anaesthetic.

In certain cases it is impossible to obtain a valid consent. With the unconscious patient the treatment immediately necessary for the relief of his condition should be given. A parent or spouse in such circumstances may give the necessary authority, and consent for any further treatment may be obtained from the patient after his return to consciousness. A practitioner may be called upon to deal with a patient requiring immediate treatment associated with serious risks if his life is to be preserved, and the conditions may well forbid legal formalities. Here again the practitioner should consult the nearest relatives, and if any treatment more extensive and irrevocable is indicated it should be deferred if possible until full consent can be obtained. A parent or guardian may give valid consent for the treatment of a minor, but if the minor has passed the age of 16, or has reached a state of mental and physical development sufficient to enable him to appreciate what it is proposed to do, his own consent should be added. When it is suspected that a person is suffering from mental or from contagious disease and is likely to be a danger to himself and to other people and cannot or will not be moved, then a parent, a relative, a medical superintendent, a householder, or a hotelier may give authority for examination, but nothing more should be done than is reasonably necessary. The consent of a spouse is not required for the administration of treatment to the other adult partner if the latter has consented; nevertheless, the consent of the other spouse in certain cases is desirable as a further insurance. A master or mistress cannot give a valid consent for the examination or treatment of a servant, and the police cannot insist on the medical examination of a person apprehended, though a person in prison can be examined without his consent by direction of the prison authorities.

Certain model forms of consent are appended to the M.D.U. document. The principal one reads:

"I . . . of . . . hereby consent to undergo the operation of . . . the effect and nature of which has been explained to me. I also consent to such further or alternative operative measures as may be found to be necessary during the course of such operation and to the administration of a local or other anaesthetic for the purpose of the same."

Much of this may seem to be a counsel of perfection. In the ordinary way if a visit is paid to a practitioner, or a practitioner is called in, consent to a certain amount of examination is implied, and this implication is good in law. Though the requirement is now common in hospitals when operative measures are to be undertaken, written consent to examination and treatment is rarely insisted on in private practice, and

still more rarely are doctors challenged in the courts on the issue of absence of consent. That in itself is a testimony to the common sense of the general body of patients and to the tact and discretion of the members of the profession. But the Medical Defence Union is aware of the legal risks to which the doctor's calling is continually exposed, and to the trouble which the querulous or litigious patient—even though he be but one in a thousand—may cause, and it has performed a useful service in preventing practitioners from being lulled into a false sense of security.

TRAINING OF NURSES

R.C.N. COMMENTS

The Royal College of Nursing has submitted to the Minister of Health a memorandum on the Working Party's Report on the Recruitment and Training of Nurses. It opens by criticizing the Working Party for making insufficient allowance in compiling its data for the handicaps which beset the nursing profession during and after the war. In order to economize nurse-power, the Royal College recommends that a job analysis be made consisting in a study of the hours of care required by various types of patients in different stages of illness, the whole team of health workers being included in the analysis. It would then be possible to allocate nursing staff in the most suitable way.

The Royal College recommends that the hours of working be adjusted so that nurses may be attracted to continue their occupation after marriage. Methods of developing satisfactory staff relationships should be studied and the part-time worker encouraged. It regrets that the Working Party did not suggest solutions to the problem of obtaining adequate domestic help.

Training should be for three years, not the two suggested by the Working Party, but the curriculum should correspond with the Working Party's suggested basic course. Pointing out that the student of nursing cannot be free to learn as she likes, the Royal College believes that the phrase "student nurse status" ought to describe more accurately the student's place than the Working Party's phrase "student status." It believes that there is need for experiment in training and suggests the following scheme:

(1) There should be one wide basic training of two and a half years' duration, corresponding in content to the basic course proposed in the Working Party's Report, with a further six months (three years in all) spent either in general or in public health nursing.

(2) At the end of three years the candidate would have a choice of two special papers, one on public health nursing and one on hospital service.

(3) Some intending public health nurses might elect to enrich their background by obtaining the full qualification in general nursing, proceeding to public health nursing as a post-certificate course.

It disagrees with the Working Party's proposals for the organization of nurses' training, considering that nursing education and research should be in the hands of the profession and that responsibility for these should be delegated to the general nursing councils. It strongly opposes the proposal that the Ministry of Health should assume such duties and functions. It considers also that the general nursing councils for England and Wales, Scotland, and Northern Ireland should remain separate bodies.

U Ba Lwin, Principal of the Myoma Co-Education School, Rangoon, is in Britain under the auspices of the British Council until June to study education, teachers' organizations, school medical and dental services, and welfare work. He is visiting social clubs, institutions, W.E.A. centres, and all kinds of schools in London and the provinces. A former student of the London Day Teachers' Training College, he is an active educationist in his own country, holding many public appointments with such organizations as Health Education Committee, Burma National Teachers' Association, Burma Education Association, and the Council of National Education. Trained in scouting at Gilwell, he is now the Burma Chief Commissioner for Boy Scouts and editor of the official organ of the Boy Scouts Association—*Burma Boy*—as well as being a member of the Girl Guides' Council.

Preparations and Appliances

A TRANSPARENT "THIRD HAND"

Dr. C. F. SCURR, Registrar in Anaesthetics, Westminster Hospital, writes: The accompanying illustration shows a modification of the anaesthetist's "third hand," devised by Magill, for use in intravenous anaesthesia. It is made from an 18 in. (45 cm.) length of 1 in. (2.5 cm.) wide transparent plastic material such as is used for making belts, braces, etc.; the

ends are slipped through a short length of rubber tubing 3/4 in. (1.9 cm.) in diameter, which provides a convenient sliding adjustment.

This device possesses the following advantages: (1) Owing to its transparency, the markings of the syringe and the position of the plunger can be clearly seen at all times. (2) The material used is so flexible that it permits secure fixation of the syringe even in very oblique positions on the forearm.

Reports of Societies

STREPTOMYCIN

A discussion on "Streptomycin" took place at a meeting of the Section of Experimental Medicine of the Royal Society of Medicine on April 13, Prof. H. P. HIMSWORTH presiding. The results of clinical trials with streptomycin in pulmonary tuberculosis and in tuberculous meningitis were brought forward. Prof. CLIFFORD WILSON also introduced the subject of the use of streptomycin in certain non-tuberculous infections, but the results in this field, he said, were not yet ready for publication.

Pulmonary Tuberculosis

Dr. GEOFFREY MARSHALL said that streptomycin had been used clinically in cases of tuberculosis since 1945, but that until the latter part of 1946 was a certain limited supply made available to the Medical Research Council. Reports from America had indicated that it was of considerable value in the treatment of tuberculous meningitis and of acute military tuberculosis; inconsistent results were reported in pulmonary tuberculosis. This chronic disease with its long course and its spontaneous remissions and exacerbations was a particularly difficult condition in which to judge the effect of treatment. Nevertheless, in January, 1947, an investigation was begun in which some 55 young adults with the typical pneumonic type of tuberculosis affecting both lungs were treated with streptomycin. The results were now being analysed for publication and all that he could do was to give a very rough and rather premature indication.

employed had been 2 g. a day, given in four injections of 0.5 g. in 2.5 ml. of water, in the twenty-four

Injections were given intramuscularly; they were rather ill, though not excessively so. Less than 2 g. a day seemed sufficient, and more than that amount seemed to be toxic, doses causing haematuria and pyrexia and other untoward effects. Side effects were relatively slight. The most important of them was disturbance of vestibular function. Though streptomycin was very effective against the tubercle, as it gradually lost its effect to a large extent in pulmonary disease. After the first six or eight weeks strains were found in sputum which were resistant. The results with the patients who had pulmonary tuberculosis were not very striking, and from the literature he had read he had not expected anything very different. But the longer the trial went on the more impressed he became, because in each of the centres—in number—in which this investigation proceeded the patients treated with streptomycin seemed to show a definite advantage over certain controls. This was shown in the conversion of the sputum from positive to negative, remission of fever, and gain in weight. At the end of six months, of treated cases, 24 were improving; on the other hand 6 patients were getting worse and 5 had died.

Another group of cases with acute miliary tuberculosis of the lung without meningitis, 13 out of a total of 24 up to the time they were doing well, 6 did well for a time but had relapsed, 5 patients had died, 2 of them with meningitis, one of six weeks and the other six months after starting treatment with streptomycin. There was no doubt about the value of streptomycin in the treatment of acute miliary tuberculosis, the clearing of the x-ray picture was dramatic. In cases of tracheo-bronchial ulceration the results had been almost constantly good; healing of the ulcers was quite rapid and nearly every case complete. Streptomycin was not worth anything by inhalation; it must be given by intramuscular injection. It had also been tried out as an "umbrella" for surgical intervention in pulmonary tuberculosis. A short course of streptomycin was given before and after resections of the lung, in some cases of extra-pleural pneumothorax a protective pleurodesis was tried. The great obstacle in pulmonary disease—not other tuberculous manifestations—was streptomycin resistance. In nearly all cases resistant strains were found developing within six or eight weeks of the inception of treatment. Variations of dose-rhythm were now being tried: instead of six-hourly, 1 g. was given in one injection each day, and in other cases one week on treatment was followed by another week off treatment, and so on. Contrary to experience with sulphonamides, it did not appear necessary to maintain a special blood-level.

Tuberculous Meningitis

Dr. TREVOR MANN gave particulars of 33 cases of tuberculous meningitis treated with penicillin. In 32 cases the diagnosis was bacteriologically proved. The discovery of streptomycin, he said, had revolutionized the approach to tuberculous meningitis. Formerly little was to be gained from the early recognition of the disease, for there was no specific treatment. The great delay in the recognition of the disease occurred in general practice, where early diagnosis was often beset by many difficulties. Confirmation of the suspicious case could not be difficult in hospital, and a positive or strongly presumptive diagnosis should be made within twenty-four hours. Several schemes of streptomycin treatment had been tried. The first continuous intramuscular and intrathecal treatment was undertaken, but it was found that many patients derived considerable benefit during intermissions of treatment. A number showed marked improvement in the mental state during a rest period, during which also the anorexia and vomiting attributable to streptomycin ceased. For a short period the intrathecal route alone was used, but owing to poor results this method was abandoned in favour of a scheme of integrated intramuscular and intrathecal treatment, with a rest period of about three weeks. Each case must be treated on its merits, and at any time it might be necessary to modify the scheme to suit the needs of a particular patient. Recently a drug had been given at six-hourly intervals, but experi-

mental evidence showed that injections every twelve hours were just as effective. Treatment should be spaced so that the intrathecal injections were given approximately midway between the intramuscular ones.

One-third of the cases showed a good response to treatment; 5 showed immediate and uninterrupted improvement. Out of a total of 15 clinically advanced cases, 13 patients were dead and 2 survived. In the case of one of the survivors the outlook was uncertain; the other was certified as recovered. Out of 13 early cases 5 patients were dead, in 5 the result was uncertain, and 3 were classified as recovered. In an intermediate group of 5, 4 patients had died, but one child had recovered and was doing very well nine months after the cessation of treatment. Psychometric tests on the 5 children who were now well showed them all to be normal. Among the advanced cases 7 were moribund on admission.

Dr. J. RUBIE mentioned a group of 47 cases of tuberculous meningitis treated at another unit. Of these 19 had survived and 8 of these had been observed over a period of 200 days, the others for shorter periods. Of the 28 patients who had died, 8 were less than seven days in hospital, and 14 were under 3 years of age.

Dr. MARC DANIELS said that, as Dr. Mann had remarked, a trial had been made in certain cases of tuberculous meningitis of streptomycin by the intramuscular route alone, under the impression that given intrathecally it had an irritative effect. Alternate cases were treated in that way. During the early months of the trial it seemed that there was nothing to choose between the two series of cases, those having only intramuscular injections doing as well as the others. After the trials had been prolonged, however, it was apparent that relapses were more frequent in these cases.

Dr. D'ARCY HART said that the factor of resistance in pulmonary cases was important in two ways. It might cause a falling off in improvement under treatment, but another consideration was that an early case with a small lesion might be treated with streptomycin and success be attained, so that treatment was stopped, but later the patient might relapse and have a positive sputum, whereupon a strain absolutely resistant to streptomycin might be encountered. It was necessary to exercise great circumspection in treating very early cases.

Dr. GEOFFREY MARSHALL said that those who had brought forward these reports had been conservative and by no means optimistic in their description, but he did not want anyone to go away thinking that streptomycin was not held in very high esteem. It accomplished what no other agent was able to do in any form of tuberculous infection. They were doing all they could to stimulate the authorities to have it introduced in large quantities. Having seen patients with tuberculous meningitis die so uniformly, it was a remarkable experience to go to Dr. Mann's clinic and to see five little children who had recovered and were living normal lives. In pulmonary disease there were cases in which streptomycin tipped the scale—for example, in the type of case in which one desired to do collapse therapy but dare not. The use of streptomycin might make other measures possible. Streptomycin was of real value and it remained to work out the best way of employing it.

WELFARE OF SPASTICS

A LONDON CONFERENCE

The medical, educational, and social aspects of the problem of cerebral palsy were discussed in London on April 14 at a conference arranged by the British Council for the Welfare of Spastics, an organization affiliated with the Central Council for the Care of Cripples and the British Council for Rehabilitation. Prof. J. M. MACINTOSH, who presided, said that when this subject was first mooted its development was attended by what he might call a certain amount of Americanism and dependence upon American experience. The subject was now becoming more of a native growth, and there were signs that in future it would develop on British lines.

Prof. ALAN MONCRIEFF said that the first paper on the subject was in 1861 by W. J. Little, the founder of what was now the Royal National Orthopaedic Hospital, though Shakespeare—

a good clinical observer, among other things—put into the mouth of Gloucester in *King Richard III* an excellent description of the condition.

The strict classification by Prof. Phelps into four or five groups was not accepted completely by neurologists in this country, nor, he thought, in the States. It was not helpful to insist too much on such rigidity. When the ultimate causation of the palsy was considered it was necessary to enter a little into the realm of speculation. In some cases the cause was lack of brain cells or malformation of the brain. A certain number—it was not known how many—were associated with obstetric difficulties. This suggested that some cases might be prevented by improved obstetric care, though it would not be fair to encourage much hope in that direction; the proportion of non-preventable was likely to remain high.

Incidence

It was not known, Prof. Moncrieff continued, how many cases there were in this country. In the United States Phelps estimated that of every 100,000 children born, 7 were afflicted with cerebral palsy, that one of those 7 would die in the early months of life, and that of the remaining 6 two would be so feeble-minded as to be ineducable, and the other 4 would be capable of education in the sense of being trained to varying degrees of efficiency by special educational methods. On these figures, in a city of the size of Birmingham or Glasgow there would be between 600 and 700 children aged up to 16 who were in the educable class. That at least was the size of the problem in America; there was some reason to believe from partial surveys that the numbers might be smaller in this country.

Why was it that this problem had only lately come to the fore? To a large extent it was due to the fact that we estimated the level of intelligence by what we saw and heard of a person, and if the muscles that controlled speech were affected a child might be classified as an imbecile, and if at the same time the muscles of the face and limbs were uncontrollable he might be put down as entirely ineducable. The merit of the work of Phelps and Carlson in the States was that they showed that some children who looked like idiots could be trained. Osler said that these people were usually more or less idiots and helpless in mind and body, but he also observed that there were some in whom the brain was not profoundly affected and a greater number who were intelligent. Osler stressed the value of massage and exercises, but massage might do harm. Occupational and speech therapy should be applied. Treatment was an expensive business, but these spastic children represented an obligation from which we could not escape.

According to Phelps, with 700 such children in a city of a million population, 140 would require in-patient and 560 out-patient treatment. At the Children's Rehabilitation Institute, Maryland, for 80 in-patient children there was a staff of one teacher, 8 occupational therapists, 8 physiotherapists, some of them undergoing training, 4 trained nurses, 24 nursing aids, and 6 porters or carriers. If the children could be brought in at an earlier age certain of this staff could be withdrawn. The need in this country was for out-patient diagnostic and instructional centres, based at a hospital, where parents could also receive instruction in the exercises to be undertaken at home, and an in-patient unit in the form of a residential school equipped for long-term stay. Prof. Moncrieff was anxious that, whatever the pattern of the organization, they should concentrate on the pre-school child.

Need for Diagnostic Centres

Dr. PHILIP R. EVANS said that it was important to know the size of this problem, and it must not be assumed that Phelps's figures necessarily applied here. During the next few years there would not be enough people trained and experienced in the treatment of these children, and therefore there would have to be some selection. On humanitarian grounds alone treatment was always worth pursuing, though in the case of children severely affected it must be disappointing. Among distinguished sufferers from cerebral palsy to some degree were, apparently, Dr. Johnson and Byron. Dr. Evans then narrated three cases in detail, in one of which the treatment was unsuccessful, the child ending in a mental deficiency institution;

in another moderately successful; while the third promised well. The cases illustrated the tragedy of failure to make an early diagnosis, though it was an extraordinarily difficult diagnosis to make during the first year or eighteen months of a child's life. The problem was to discover damage to the nerve system at an early period.

Mr. GEORGE TOMLINSON, Minister of Education, who opened a later session, said that the treatment of these handicapped children was still in the experimental stage. Those engaged in this work could be assured of his support and the support of everyone in his Ministry. This session was on the educational and psychological aspects and was addressed by Dr. E. MILDRED CREAK and by Miss M. I. DUNSDON, director of research in the problems of educating spastic children, National Foundation for Educational Research. A final session dealt with the social aspect of the problem.

FENESTRATION OPERATION FOR OTOSCLEROSIS

At a meeting of the Liverpool Medical Institution on March 11 with the president, Prof. T. P. McMURRAY in the chair, Mr. JOHN MCFARLAND read a short paper on the surgical approach to the inner ear.

Mr. McFarland said that in the relief of deafness in otosclerosis a window was made in the bony lateral semicircular canal or ampulla. A tympano-meatal membranous flap was fashioned and placed over it (after Lempert). The surgical approaches for the procedure were described, the speaker favouring the incision and technique of Kettel. Two cases thus treated were shown, and in addition a woman of 31 whose hearing had considerably improved following fenestration by a different technique. A Thiersch graft was placed over the window, the edges of which were impregnated with lead to prevent osteogenesis; the mastoid wound was filled with penicillin powder and closed without drainage. The wound healed by first intention in ten days; the tympanic membrane became normal in five weeks, and the patient heard in six weeks.

In the discussion which followed, Dr. H. ZALIN said that the fenestration operation for otosclerosis provided considerable scope for variation and ingenuity in the method of approach and technique. There was a danger of over-concentration on minutiae to the exclusion of an unbiased assessment of results. The cause of otosclerosis remained unknown. The mechanism whereby fenestration improved hearing in otosclerosis was equally mysterious. A more cynical approach to the problem would do much more good than harm. Devices intended to maintain a continuously patent opening had varied from metal obturators to acrylic inserts. Enthusiastic operators quoted hundreds of cases treated with dramatic effects by one method—and then suddenly switched to a variation. The multiplicity of changes in technique shown by one surgeon alone in the past five years indicated a dissatisfaction with the results not visible in the published cases. The main difficulty was the maintenance of a small stoma in bone which tended to form new bone as part of the essential pathology of the disease. The following facts had been observed at Bootle General Hospital: (1) a post-operative improvement in hearing in a number of cases in the unoperated ear; (2) in successful cases bizarre sensations of sound had been noted; (3) increased sensitivity to pure tone was seldom accompanied by a corresponding improvement in intelligibility.

Dr. Zalin asked: Is it possible that an increase in the sensitivity of the end organ to sound is related to labyrinth trauma alone? Does the cochlea become more sensitive than before operation in the same way that a tooth becomes more sensitive when it develops a dental abscess? Will the end result be disappointing not because of inadequacy of technique but because the procedure, based as it is on so little scientific knowledge of the aetiology, is possibly doomed from the start? At the same meeting Mr. J. P. HERON read a short paper on maternal obstetric palsy, and Mr. F. C. DWYER read a paper on tenosynovitis stenosans.

Correspondence

Dr. Dain on the Plebiscite

SIR,—The speech I made at Shrewsbury last Sunday, which received much publicity in the Press, seems to have caused some misunderstanding in the profession. I should like to make it clear that I depart in no way from the careful and balanced statement issued by the Council to every doctor in the country. The Minister of Health's concessions present us with a changed situation which makes the new plebiscite necessary.

I would urge that it is the duty of every doctor to make up his own mind on the facts, and to decide whether Mr. Bevan's concessions go far enough to safeguard the essential professional freedoms of the practising doctor.—(I am, etc.,

B.M.A. House,
Tavistock Square,
London, W.C.1.

H. GUY DAIN,
Chairman of Council

Anti-Rh Serum Nomenclature

SIR,—In the annotation on "Anti-Rh Serum Nomenclature" (Feb. 28, p. 400) you discuss the recent edict of the National Institute of Health in the United States regarding the labelling of anti-Rh sera, namely to use the earlier Wiener Rh-Hr system as standard, with the corresponding Fisher-Race C-D-E notations in parentheses. You regard this decision as a "transitional compromise," implying that eventually the original notations will be abandoned in favour of the Fisher-Race system. However, this conclusion as well as the Board's own analysis fails to take into account all the available facts.^{1,2,3,4} I have therefore prepared my own analysis of the situation, and after it is printed in your journal perhaps one of the C-D-E protagonists will attempt a reply. Only by publishing all the facts and both sides of every scientific problem can we ever hope to arrive at the correct solution.

Advantages of the Rh-Hr Nomenclature

1. They have priority, having been proposed by one of the discoverers.
2. They form a coherent and unified system, which readily lends itself to extension to include newly discovered blood factors belonging to the rhesus system.
3. The genetic theory on which the notations are based is amply supported by heredity studies on a large series of families, and statistical studies on the distribution of the types in the population. On the other hand, there is no evidence against the theory.
4. The notations are simple to use in writing and orally.
5. The notations clearly separate the designations for phenotypes and genotypes, and for agglutinogens and genes, leaving no room for ambiguity.
6. The phenotypes' names clearly indicate what tests have actually been made and what reactions were obtained, without including symbols for hypothetical blood factors which have not been tested for, and for which there is no clear experimental evidence.
7. The notations clearly indicate the relationship to the original rhesus factor, and separate the Rh-Hr types from other independent systems such as the A-B-O groups and M-N types.
8. For individuals who already know and understand the four blood groups and the three M-N types, the Rh-Hr notations are easy to learn almost instantaneously.
9. The notations lend themselves readily to clinical use, since the capital R's and small r's clearly indicate which types are Rh-positive and which are Rh-negative.
10. They take advantage not only of the reciprocal relationship between the Rh and Hr factors, but also of the special clinical, serologic, and genetic position of factor Rh.
11. They do not involve any incorrect assumption of one-to-one correspondence between genes and partial antigens.
12. They are self-sufficient.
13. None of the symbols used in the Rh-Hr notations have previously been applied to other agglutinogens.
14. The notations as used by workers throughout the world are uniform.
15. Simple tables are available for the Rh-Hr types and their genetics.

16. They are the *only* notations used in most standard textbooks, encyclopaedias, dictionaries, and articles.

Supposed Disadvantages of the Rh-Hr Notations

1. That they take longer to teach. Where this seems to be so, it is merely because one must *understand* the Rh-Hr types in order to use the Rh-Hr notations intelligently, and to teach them.
2. That they have been changed several times. This is true, but none of the changes are basic or really upsetting. Moreover, one need only learn the present nomenclature to understand the subject. The changes have served to improve and streamline the nomenclature, and are no more objectionable than the changes made from year to year in order to improve the performance and appearance of automobiles. One does not have to study the entire evolution of the automobile from 1905 to date in order to learn how to drive one's 1948 model.

Supposed Advantages of the C-D-E and Rh₁-Rh₂-Rh₃ Notations

1. Many workers have the false impression that they are easier to "learn" and teach. The reason for this is that one can speak about C-D-E and Rh₁-Rh₂-Rh₃ at once, without having any real understanding of the subject. These notations therefore serve as a convenient cloak for lack of knowledge and understanding, and actually discourage any desire to acquire such an understanding.
2. They make use of a one-to-one correspondence between genes and blood factors. This supposed advantage is based on the wrong concept that such a one-to-one correspondence must exist, which is not true.
3. They are gaining more adherents. This is true only because the protagonists of this system are teaching it, and because the new regulation passed by the National Institute of Health has forcibly called these notations to the attention of workers. The C-D-E and Rh₁-Rh₂-Rh₃ notations will naturally attract some adherents, just as the Moss and Jaosky systems each gained their adherents. The resulting unnecessary confusion may take many years to clear.

Disadvantages of the C-D-E, Rh₁-Rh₂-Rh₃, and other Systems

1. They lack priority.
2. The genetic theory on which they are based is purely theoretical; there is no experimental evidence to support it, nor does it lend itself readily to experimental attack. On the other hand there is some statistical evidence based on the analysis of the distribution of the Rh-Hr types in the population that tends to refute the linkage idea.
3. The notations are cumbersome to use. For example type rh becomes small-c, small-d, small-e over small-c, small-d small-e. An error in printing in which a capital letter is substituted for a small letter or *vice versa* could prove fatal. Thus if anti-d is written instead of anti-D this would be very serious, but if anti-rh, is written instead of anti-Rh, the intention of the writer would still be obvious.
4. There is no clear separation of phenotypes and genotypes. The use of designations for "the most likely" genotype without indicating clearly all the time what is intended conveys to the reader the false impression that the actual genotype has been determined. The writings of users of these notations continually confuse genotypes with phenotypes, and it is impossible to tell from the designation used what tests have actually been made.
5. The letters C-D-E give no indication of any relationship to the rhesus system and convey instead the erroneous impression of a relationship to the A-B system of blood groups.
6. To learn the other notations suggested one must start from scratch, and all one's knowledge and understanding of the A-B-O and M-N systems is wasted.
7. The notations are too awkward for clinical use. There is no clear indication in the notations which bloods are Rh-positive and which are Rh-negative.
8. While some of the proposed systems of notations take advantage of the reciprocal relationship between the Rh and Hr factors, none takes into account the special clinical, serologic, and genetic position of the factor Rh.
9. The notations are not self-sufficient or self-explanatory. Thus users of the C-D-E notations are compelled also to use the Rh-Hr notations, as can be seen by consulting the papers of Fisher and Race who originated the C-D-E notations.
10. The symbols C and E have already been applied to other agglutinogens in human blood. The introduction of the use of these letters for agglutinogens of the rhesus type would therefore result in ambiguity.
11. There is no uniform understanding among users of the C-D-E notations as to terminology for the phenotypes. Thus blood reacting with "anti-C," "anti-D," and "anti-e" but not with "anti-E" is variously designated as CD_e, or CeD_e, or CD_e/cde, etc. Under the Rh-Hr notations, the blood would be designated

simply as Rh_h, a name which clearly indicates positive reactions with sera anti-rh', anti-Rh_h, and anti-hr', and negative reactions with anti-rh'.

12. No simple unified tables regarding the types and their heredity involving the other proposed systems of notations are available for use.

13. The C-D-E and other proposed notations are not mentioned in most standard laboratory texts, and are therefore unintelligible to the average reader.

—I am, etc.,

New York.

Scepsis Scientifica

SIR,—In his interesting address Prof. Geoffrey Jefferson (Feb. 28, p. 379) asks, "Could anything be learned from the structure and workings of the brain?" From the context this seems to refer to the relations of the brain to mind. He answers the question by saying that "to this old question we have no modern answer."

The *Proceedings of the Royal Society of Edinburgh*, Section B (Biology), 1943-4, Vol. 62, Part I, p. 86, gives at least one "modern answer."—I am, etc.,

Perth.

R. J. A. BERRY.

*. The reference is to an address entitled "Some Recent Advances in the Study of the Brain as the Implement of the Mind" which was read by Prof. Berry to the Royal Society of Edinburgh on June 5, 1944.—Ed., *B.M.J.*

SIR.—I read Prof. Geoffrey Jefferson's article (Feb. 28, p. 379) with such keen appreciation and enjoyment that it seems ungrateful to suggest that the issue might have been made clearer in the final paragraphs. The use of words as an economy of thought, to which the human race owes so much, is sometimes more confusing than helpful. Prof. Jefferson writes, "There are other large fields of knowledge besides Science." The meaning of these words as they stand alone is not very clear; but the important underlying meaning, obvious from the context, is that scientific technique is suitable for the investigation of some but not all of our total experiences.

The confusion arising from the use of the term "Science," at one time in its literal sense of knowledge, and at another in its acquired sense of a definite technique (deduction combined with induction, with special emphasis on the appeal to experience), has established a sort of vicious circle. Science in its meaning of scientific technique has had dramatic triumphs in the investigation of certain fields of our total experience, such as chemistry and physics, and has given us valuable knowledge of these subjects. These great successes naturally raised hopes that Science would be equally efficient in supplying knowledge in all other fields. But if we employ a word which means by derivation "Knowledge," not only for the knowledge obtained by a special technique but also for the technique itself, it is an easy step by equating all knowledge with the special technique to prejudge the whole issue and to obscure the truth, emphasized by Prof. Jefferson, that scientific technique as a means of winning knowledge is not infallible nor even suitable in all fields of our total experience.

This belief in the total infallibility of scientific method has become firmly established in the popular mind, largely owing to the dual meaning referred to above which has become attached to the term "Science," and it is this misconception which is threatening our civilization with disaster to-day.

As scientific technique invades the higher fields of biology and psychology it is compelled willy nilly, in order to maintain its output of success, to appropriate more and more to its use those techniques such as intuition and introspection which are suitable to these higher levels, and we are sometimes surprised to realize that these higher techniques have now been quietly incorporated in the scientific method. Unfortunately the highest techniques of all, meditation and love, have not yet been officially adopted, although to the writer it would seem just as much as error of technique to attack the problems of, for instance, social psychology by the scientific method, unaided by meditation and love, as to endeavour to analyse or weigh a chemical substance by meditation and love unaided by the scientific method.

Of course there is not the slightest objection to combining all techniques, including meditation and love, under the heading of "Scientific Technique" if we wish; but we might then just as well call this all-embracing technique "Religion." This brings us back to our old friend and enemy, the use of words.—I am, etc.,

London, S.E.21.

M. H. K. KANE.

Temperature Records and Ovarian Activity

SIR,—The letter by Dr. P. M. F. Bishop (April 10, p. 706) reflects certain common misconceptions concerning the significance of temperature records in the study of infecundity. May I attempt to clarify the position within the space available for a valuable clinical method be employed without due regard for either its potentialities or its limitations? Dr. Bishop asks few questions.

Question No. 1: Does the basal temperature pattern denote whether ovulation has taken place?—The occurrence of a biphasic temperature cycle indicates that a phase of oestrogenic secretion has been followed by a phase of progesterone secretion. The rise of temperature caused by progesterone is usually, but not invariably, associated with, or follows upon, ovulation. But progesterone may be secreted without actual liberation of an ovum (e.g., in the case of retained ova or of luteal cysts), so that the rise is no absolute proof of ovulation. Conversely, ovulation may occur without luteinization, so that the absence of the typical rise in temperature may not prove the absence of ovulation. The condition of the endometrium also depends on ovarian secretion, not on ovulation itself. But the association between ovulation and a biphasic temperature curve is so high that in practice it has been used by a number of independent workers for timing of intercourse or of artificial insemination.

Question No. 2: Can it indicate exactly when ovulation takes place?—Experience with artificial insemination and with laparotomies timed in relation to the temperature cycle (cf. Greulich, W. W., Morris, E. S., and Black, M. E., *Proc. of the Conference on Problems of Human Fertility*, 1943, p. 37) show that ovulation, which of course is not necessarily an instantaneous process, tends to coincide with the thermal shift from the low to the high level. The accuracy of timing depends among other factors on the rapidity of the rise and is, therefore, less reliable in cases where the shift is of the gradual ("staircase") type.

Question No. 3: What information does it provide us to the degree of ovarian activity?—Injection of natural oestrogens tends to lower the level of the temperature. In women with anovular cycles and a high level of oestrogenic secretion (e.g., in certain cases of glandular cystic hyperplasia or ovarian cysts) the waking temperature remains permanently at or below the level characteristic for the follicular phase; injections of progesterone raise the waking temperature to the level normally prevailing during the luteal phase according to the dose given. Again, during the early phase of pregnancy when the progesterone level is high the temperature is also high. When the progesterone level falls during pregnancy (e.g., in imminent abortion, or during the fourth month of gestation) the temperature drops, but rises again in response to progesterone injections. These are but some of the facts which indicate that the actual level of the waking temperature, as well as its relative variations, reflects quantitative variations, and not only the phases, of ovarian activity.

Question No. 4: Is it likely to give more accurate information than the temperature is recorded rectally than if it is taken by mouth?—The oral temperature is apt to give occasional deceptively low readings, due to extraneous factors such as mouth-breathing, to which the rectal reading is not susceptible. This means that in any individual case the oral temperature may show a misleading value, so that the subject might miss a critical date, if I may use this expression.

Dr. Bishop also contrasts the 500 records collected at the Family and Endocrine Clinic of the Chelsea Hospital for Women during the past three years with the large number to which I refer. Perhaps there is some confusion between number of women entered and number of cycles recorded. It has been my practice to ask patients to record the waking temperature for not less than three months, and quite generally until they have reached the fourth month of pregnancy or their case has been discontinued. In one case illustrated in the original communication (*Lancet*, 1945, 2, 46), Fig. 6) 26 successive cycle records from one patient were reported, and more than 1,500 records gathered from private practice. Of course since then the work has been much extended by private and others. It is a fact long recognized that successive menstrual cycles differ from each other with respect to occurrence of ovulation, duration of luteal phase, etc., and it is quite justifiable in the treatment of infecundity to record only one cycle or even two.

cles. Continuous records are part of the proper background for the diagnosis and treatment of infecundity, also for the supervision of pregnancy in its early stages.

Concerning the statistical evaluation of the extensive data available some results have already been published (see Fig. 2 in the paper quoted; also Figs. 100 A-D inclusive, in Siegler, S. L., *Fertility in Women*, London, 1944; also Palmer, A., 1942, *Surg.ynec. Obstet.*, 75, 768). These show mean rectal readings on suitable grids. Further statistical evaluation of data will be useful in some respects, but Dr. Bishop overrates the function of statistics if he thinks that the statistical evaluation of temperature readings taken by themselves can solve such questions as to whether ovulation is denoted by any given pattern. They can only be used for this purpose when related to some different and direct indicator of ovulation such as findings at laparotomy.

I would add that my experience is not "unique," as can be readily ascertained by anyone who cares to avail himself of the extensive literature on the subject which has come into being in the last ten years.—I am, etc.,

London, W.1.

MARY BARTON.

Identification of Medical Documents

SIR.—It appears to me that Prof. Lancelot Hogben and others (April 3, p. 632) are trying to make a mountain out of a molehill. We are, presumably, on the eve of a National Health Service. If code numbers can be supplied to death certificates, why not to birth? These could be used for the medical histories.

I have been told that Records Officers have experienced difficulty in obtaining National Registration Card numbers, but after 30 years' experience of giving identification numbers to my patients I am convinced that where the Records Officer may fail the doctor never will if he is worth his salt.—I am, etc.,

Hatfield

A. GARVIE.

Treatment of Phlebothrombosis

SIR.—Mr. Hamilton Bailey's article (March 27, p. 594) is both timely and welcome, and it should serve as a stimulus to the earlier detection of phlebothrombosis. It would be a pity, however, if the impression is gained that all such cases should be treated by interruption of the vein.

Since 1944 I have been on the look-out for this condition and have performed the operation in a number of cases. I have been impressed at the number of times the condition can be spotted if one remembers to look at the legs after the fourth post-operative day. My own feeling is that the large majority of cases are best treated with anticoagulants. I have tried to confine, for my own benefit, the indications for operation as against anticoagulative therapy, and I have come to regard them as follows:

1. Where anticoagulants are not available—this was so in three of the casualties.
2. Where haemorrhage follows the use of anticoagulants. In recent case of spreading thrombosis and pulmonary infarction on 7th day following prostatectomy, profuse haemorrhage occurred on the prosthetic bed when heparin was given.
3. Where anticoagulant treatment would have to be maintained for many months and active leg movements are prohibited, as in case where phlebothrombosis develops during heart disease.
4. Where there is recurrent phlebothrombosis—e.g., in 1943 and 44 repeated small emboli with pulmonary infarction occurred at intervals of a few months in a serving soldier. Each attack was severe enough to require hospitalization. Venous interruption has given him complete relief.
5. Where there is obvious arterial disease contraindicating anti-coagulants. In one case I have seen cerebral haemorrhage follow their use.
6. Where extensive ulcerating lesions are present—e.g., ulcerative lesions from which haemorrhage is to be feared.

In the actual operative procedure I have made it a practice to expose the external iliac vein and not the femoral. There is some evidence that the collateral circulation is more efficient here than low Poupart's ligament.

I have found a glass tube of a diameter a little less than that of the external iliac at this site to be the most efficient extractor of clot. The tube must be angulated 135° at about 6 in. from the tip. A powerful suction apparatus is required, and the glass tube gently pushed up inside the vein, thus detaching the clot where it is adherent

to the intima. As the clot gradually becomes free it can be watched passing up inside the glass tube until the upper limit of attachment is reached, when it is suddenly sucked down the tube, often in one piece.

It is wise to have the patient half sitting-up during this stage of the operation, and as soon as the clot is free he should be instructed to hold his breath so that the blood flows back down the vein. Pain in the calves usually disappears within 24 hours of the operation.

I have never regretted carrying out this operation, though I have once regretted that I did not tie the opposite vein as well. At the same time I think it would be unwise if the vein was ligated in every case of deep thrombosis. In the majority of cases all that is needed is treatment with heparin and dicoumarol. The difficulty which arises is to determine the cases in which vein interruption is preferable.—I am, etc.,

Bristol, 3.

W. M. CAPPER.

Harrison's Grooves

SIR.—The article by Drs. J. Naish and H. R. E. Wallis (March 20, p. 541) on the significance of Harrison's grooves is an interesting work of research into the historical aspects of the problem. It is rather difficult, however, to agree with them in their explanation of the mode of occurrence of this clinical feature. If the ribs buckled along the line of separation of the "vertebro-sternal" from the "vertebro-chondral" ribs, such an effect would be produced maximally in cases where the intercostal muscles are strongest and the negative intrathoracic pressure most evident. In complicated pneumonia there is very little alteration in the intrathoracic negative pressure; certainly there is no increase in the elastic recoil of the lungs in this disease. If bronchiectasis followed the pneumonia a varying amount of elastic tissue will have been lost, leaving the patient with less elastic tissue than previously. In any case if one is concerned chiefly with a disproportion between the negative pressure in the thorax and overacting chest muscles, one is still met with the fact that the diaphragm helps to fix the anterior portions of the lowest ribs, whose lateral portions tend to move outwards.

I agree with Dr. R. Good (April 10, p. 707) that an analysis of the problem should include a consideration of the question of position, though it is felt that he does not sufficiently stress the significance thereof. On the other hand it is difficult to agree that feeding is a matter of much importance. Feeding *per se* affects 100% of children; Harrison's grooves are not found in more than about 10%, and in any case they develop more commonly in children after illnesses in which anorexia, and therefore a diminished food intake, are clinical features. This of course does not rule out the part played by abdominal distension whether by aerophagy or by fermentation, in the intestines of a weakened infant.

However, I think more light will be thrown upon this clinical sign by considering in greater detail the incorrect posture in which many patients are nursed during several phases of their illnesses. The so-called "upright posture" frequently consists of flexion of the head and neck, of the upper part of the chest upon the lower, of the abdomen, of the knees, yet minimal flexion of the hips. It is enforced yet concealed by the tucking in of the bedclothes, which are rendered heaviest and tightest under the chin and over the shoulders in a patient who has partly slipped down—i.e., the custom of "tidying the bed" or making the patient "comfortable."

Where the best of nursing facilities exist—and certainly in the best of children's wards—such a posture is practically unknown. In many other children's hospitals, and in more than one adult ward, if understaffed, this "decubitus *en flexion*" has been encountered with somewhat more than slight frequency. It explains why lumbar rather than sacral pads of oedema sometimes develop in patients suffering from cardiac failure who are treated in bed in this manner.

An examination of conditions obtaining in the patients' homes will support this point of view. Especially in the case of the poorer ones—from which many of the patients observed by Drs. Naish and Wallis came—and particularly where the sick child has been nursed in its parents' bed because other facilities are even less suitable, the posture described above is the usual finding. It is perpetuated when the debilitated convalescent child or one suffering from repeated attacks of asthma or recurrent mild infections is made to rest in a high and large adult's arm-chair with only his head, shoulders, and sacrum in contact with any support.

The result—as Dr. Good pointed out, displaces anteriorly and outwards the soft lower ribs by the action of the tense upper abdominal contents. It diminishes respiratory excursion and mini-

mizes the power of the abdominal muscles in the action of coughing. In this flexed position, if the rectus abdominis exerts any action at all, it tends to pull the 5th, 6th, and 7th costal cartilages *forwards* as well as *downwards*. Only when the child completely recovers from his pulmonary or other disease and is able to get about actively does the rectus abdominis, aided by the transversus thoracis, act in a truly vertical direction anatomically. But not all the child's natural and unbiased instincts are sufficient to compensate for the errors committed upon him during his periods of enfeeblement by his elders—and "betters."

Perhaps one piece of evidence to support this explanation is the fact that Harrison's grooves, although commonly found in children who have chronically infected tonsils, do not occur particularly in those who have had diphtheria or meningitis—cases nursed in bed in the supine position. Lastly, it may be mentioned that one's study of human beings is necessarily incomplete if while pursuing such a study one does not oneself also consider them in the normal habitat—namely, the home. If one did it would soon become manifest that the "upright attitude" of man, though often "assumed," is not always "true."—I am, etc.,

London, N.4.

I. H. MILNER.

Thiouracil in Toxic Goitre

SIR,—I have been tempted to enter the lists on the discussion of the value of thiouracil in thyrotoxicosis following on the paper by Drs. Harold Cookson and F. H. Staines (Nov. 15, 1947, p. 759), the letter by Mr. Geoffrey Keynes and Dr. J. W. Linnell (Dec. 13, p. 971), and the reply by Drs. Cookson and Staines (Jan. 7, p. 123). In the past 30 years I have had an extensive experience in the surgery of the thyroid gland, and since the introduction of the "thio" drugs I have used them extensively in two ways: (1) as short-term treatment in preparation for operation of nodular or, as I prefer to term them, toxic adenomatous goitres, and (2) as long-term treatment for the acute primary hyperplastic toxic goitres, practically all patients being ambulant. I would draw particular attention to these two classes, as the adenomatous and old colloid goitres with secondary thyrotoxicosis are unsuitable for long-term treatment with the prospect of cure, as they invariably relapse and, provided they are operable, should be subjected to surgical treatment.

With acute primary thyrotoxicosis, however, the position is very different—in fact just as different as the pathological condition of the glands in primary and secondary thyrotoxicosis. In my last published report on the control of thyrotoxicosis by methyl thiouracil (*Med. J. Aust.*, 1947, 2, 93) I presented a detailed and critical survey of 84 patients with long-term treatment by methyl thiouracil, which I find is the drug of choice. There were fifty patients of the acute primary type in whom treatment had been concluded for varying periods and fifteen in whom it had not been concluded. Of these, four had been subjected to operation—one because she was subsequently found to be a secondary type, one for cosmetic purposes, and two because of reactions to the drug. There were nine patients with toxic adenomatous glands who had been on long-term therapy for various reasons, and three of these had finally been brought to operation. There were ten recurrent primary cases following either operation or x-ray therapy, of whom six had their treatment concluded with satisfactory result. One was referred for further deep x-ray therapy and three were still under treatment. There were no deaths, and only in eleven cases were there any reactions which could be classed as toxic. In four of these I do not consider that the drug was an aetiological factor, but as the various troubles developed during treatment they were included. In only three cases was treatment suspended, operation being carried out in two of them and the third referred for deep x-ray.

As Mr. Keynes mentioned, surgery in expert hands carries with it a mortality of less than 1%, but this depends not only on the surgeon but on his team, as the anaesthetist plays a very important part, as do the nurses concerned in the immediate post-operative course, and I still believe the average surgeon in this field has about a 5% mortality. Surgery carries with it other than mortality risks, such as laryngeal nerve paralysis, hypoparathyroidism, and residual toxicity, and if 80% of cases are eventually restored to complete normality by surgery it is good work. In my own cases of acute primary thyrotoxicosis I now subject them all to long-term therapy with methyl thiouracil and necessary adjuvant therapy, as I have laid down, for in 87% of cases apparent cure can be obtained, and if surgery is decided on later it can be carried out with safety. My own experience

confirms that of the Lahey Clinic in that I have not had a fatality in over 300 cases of toxic goitres since preparation has been carried out with thiouracil.

Mr. Geoffrey Keynes and Dr. Linnell give a very caustic criticism of the results obtained by Drs. Cookson and Staines, and without some justification, as they compare very unfavourably with those published by other workers (possibly because only ten of the 95 cases were "smooth" goitres), but I feel that their implied contention that all cases of thyrotoxicosis should be operated on is incorrect, and even in the Lahey Clinic one can see they are departing from this rigid standard laid down in their early experience of the "thio" drugs that surgery was the only cure. I would also point out that most workers in this field experience too many technical effects, due, I consider, to too high dosages, insufficient clinical observation of the patients, adherence to a standard and not individual routine, neglect of adjuvant therapy, and persistence with long-term treatment in cases of secondary thyrotoxicosis.

In over 500 patients treated with "thio" compounds or with treatment, whether short- or long-term, I have had one case of agranulocytosis only, and less than 7% of toxic manifestations which are mainly so mild as not to interfere with treatment. The average time of treatment is about 7 months, and so far only 1% of recurrences have occurred, as contrasted with the 48% of a combined series of reports from U.S.A. and the 16% of Drs. Cookson and Staines. Dr. A. Wilson and Prof. H. P. Himsworth so far give the most encouraging results from Great Britain in the field of long-term treatment with thiouracil or methyl thiouracil, and it is hoped that other workers will publish their experiences, as it is only by free exchange of ideas and results that we can determine what is best for each individual patient. After all this is what constitutes our ultimate responsibility to the general public.

I would like to support the remark of Drs. Cookson and Staines that antithyroid drugs have established themselves as a most valuable addition to the methods of treatment of toxic goitre, and in certain types as the method of choice, and recommend it to Mr. Geoffrey Keynes and Dr. Linnell for their further unbiased consideration.—I am, etc.,

Sydney.

HUGH R. G. POATE.

Calciferol in Tuberculosis

SIR,—Although calciferol has become established as a valuable therapeutic agent in lupus vulgaris, its use in the treatment of pulmonary tuberculosis is regarded with diffidence. Literature on the subject is scanty, but the report by Macrae (*Lancet*, 1947, 1, 135) appears to justify caution with this method of therapy. He records disastrous results to two patients undergoing treatment for lupus. One had a fatal haemoptysis, the other developing active disease in the lung, which fortunately subsided after the calciferol was withheld. Neither of these patients exhibited evidence of pulmonary involvement prior to the commencement of treatment.

In the treatment of established phthisis, however, calciferol may be of value and the dangers of its administration exaggerated. Dr. R. Grenville Mathers (March 20, p. 56) observed clinical improvement in six cases of advanced pulmonary tuberculosis treated by this method. No adverse effects were noted. I have obtained similar results in ten patients, giving them weekly injections of 500,000 units for periods varying from six to twelve weeks. Moreover I have observed a greater clinical and radiological improvement when this treatment was combined with the administration of "promantol." All the cases were of the very advanced and febrile type, and progress has exceeded that which I would have expected from bed rest alone.

Results so far have led me to conclude that calciferol may become a useful adjunct to the treatment of phthisis, but the uncertainty of its action does not yet justify its application in those cases suitable for more orthodox measures. If calciferol acts by stimulating the defence mechanism of the tubercle bacillus, it may prove a more effective means of treatment when used in conjunction with chemical agents acting on the tubercle bacillus itself, such as streptomycin, sulphatone, or sodium para-aminosalicylate. The improvement seen with promantol gives support to this suggestion. Further research into the mechanism of action is necessary and it would be interesting in the meantime to hear from others who may have used this drug for the treatment of phthisis.—I am, etc.,

St. Helens, Lancs.

D. S. HALL.

BRONCHIAL ASTHMA

The effect upon the bronchial musculature is among the selective mechanisms of action of the drug *Cardophylin*: it appears that the seat of its bronchial antispasmodic action is peripheral and due to direct depression of bronchial smooth muscle.

Cardophylin

THEOPHYLLINE-ETHYLENEDIAMINE

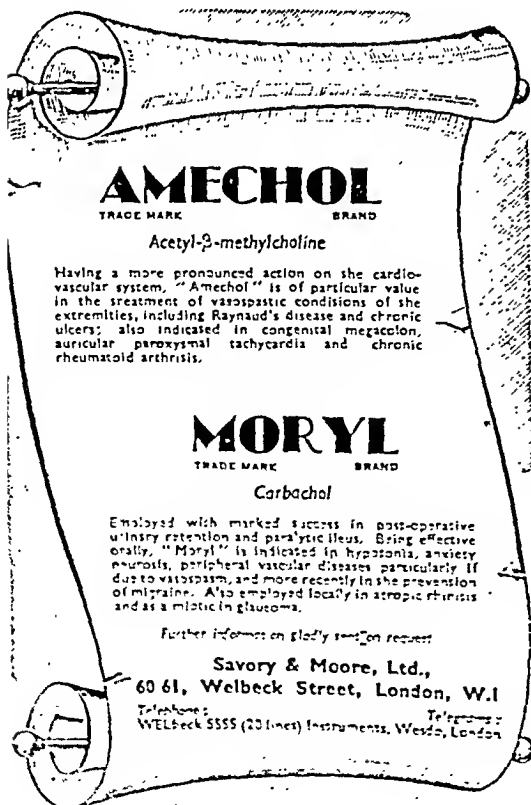

INDICATIONS
BRONCHIAL ASTHMA
PAROXYSMAL NOCTURNAL DYSPNOEA
DISEASES OF THE CARDIO-VASCULAR SYSTEM OEDEMA

In 10 L's (containing 0.1 gm.) for oral use. Suppositories (containing 0.30 gm.). Ampoules; Intramuscular (containing 0.15 gm. in 2 c.c. water). Intravenous (containing 0.24 gm. in 10 c.c. water).

AMECHOL
TRADE MARK BRAND
Acetyl-β-methylcholine

Having a more pronounced action on the cardio-vascular system, "Amechol" is of particular value in the treatment of vasospastic conditions of the extremities, including Raynaud's disease and chronic ulcers; also indicated in congenital megacolon, auricular paroxysmal tachycardia and chronic rheumatoid arthritis.

MORYL
TRADE MARK BRAND
Carbachol

Employed with marked success in post-operative urinary retention and paralytic ileus. Bring effective orally, "Moryl" is indicated in hypotonia, anxiety neurosis, peripheral vascular diseases particularly if due to vasospasm, and more recently in the prevention of migraine. Also employed locally in atrophic rhinitis and as a miotic in glaucoma.

*so to bed...
and so to rise*

REFRESHED • RESTORED • REVITALISED

'Tabloid' Cyclobarbitone is the ideal barbiturate for routine sedation. It induces sleep within one-half to one hour, after which its hypnotic action rapidly diminishes and is replaced by a state of *natural* sleep. The patient awakes refreshed and free from the "hang-over" effects commonly produced by soporific drugs.

'TABLOID' Cyclobarbitone

BURROUGHS WELLCOME & CO. (The Wellcome Foundation Ltd.) LONDON

For promoting
*Natural
Restful
Sleep*

THE control of insomnia presents a problem that often cannot be effectively or safely solved by recourse to the use of hypnotic drugs.

'Ovaltine' provides a safe and natural means of inducing sleep in many cases, especially where the basis of the insomnia is digestive unrest, nocturnal hunger or nervous instability. Taken before retiring, it promotes quiet and restful sleep by reason of its gentle sedative effect on the nervous system and its faculty of assisting digestive ease.

'Ovaltine' is a natural food tonic prepared from milk, cereals, fruit extracts, cocoa and eggs. It is powered of a truly delicious taste and is appreciated by every type of patient.

Hospitality for Overseas Visitors

SIR.—The Empire Medical Advisory Bureau has now been up by the Council of the British Medical Association (*vide* Annual Report of Council, 1947-8, *Supplement*, April 10, p. 68). One of the aims of the Bureau is to arrange for private hospitality in doctors' houses to medical visitors from overseas, particularly those from the Dominions and Colonies. Several medical men, despite present-day difficulties of rationing (and rationing!), have expressed a desire to meet and entertain in various ways overseas postgraduate students, who are often at a loss for friendly contacts, particularly in the early stages of their stay in this country. A week-end in the country or by the sea would be a delight and refreshment to men who spend their weekdays in unaccustomed grimy cities.

May I appeal through your columns to the generously hospitable instincts of our members to help make our overseas visitors welcome in their visits "home." I shall be very glad to see doctors willing to offer hospitality to our overseas visitors for one or two days or even longer would write to me stating what they are able to offer.—I am, etc.,

Empire Medical Advisory Bureau,
B.M.A. House,
Tavistock Square,
London, W.C.1.

H. A. SANDFORD,
Medical Director.

"human approach," and in the possession of a broad general ability—that there should be a potentiality both of prestige and financial reward in general practice. There should be some criterion by which a general practitioner can be recognized as outstanding, much as a physician gains prestige from his honorary appointments or his Fellowship.

Neither the F.R.C.S. nor the M.R.C.P.—not even an M.D.—are relevant to this case. They do not judge the qualities necessary. But it should be possible to institute some diploma which could only be gained by a man who has had, say, ten years in general practice and kept up with advances in medicine, while eschewing mumbo-jumbo, rule of thumb, and quackery. If the possession of such a qualification carried a high financial reward—say, a double capitation fee—it would enormously alter the feelings of the best newly qualified men about general practice, and would attract them where they are needed, instead of their swelling the ranks of the minor specialists.

Such a diploma should not be obtainable by cram courses at hospitals; it should not involve a knowledge of the rare diseases. It would judge qualities which are difficult to test, but it could be done. Without it the G.P., in a generation of State practice, will degenerate into a filler of forms and a prescriber of placebos.—I am, etc.,

Ashted, Surrey.

W. EDWARDS.

The Minister's Assurances

SIR.—The National Marriage Guidance Council relies largely on the help and advice of the medical profession in its effort to educate the public in preparation for marriage as well as in its important work of reconciliation in the cases of broken marriages and marriages. The interest of practitioners and specialists, who can subscribe to the principles upon which the National Marriage Guidance Council bases its work, is now being cited even more urgently. Local B.M.A. Groups, at one of their meetings perhaps, would be willing to accept the services of a speaker on the medical aspects of marriage guidance, and a discussion helpful to both sides might be arranged.

The Council would be glad to arrange for talks by medical representatives of the National Marriage Guidance Council if a request for such a talk is sent to the Secretary of the Medical Committee, National Marriage Guidance Council, 79, Duke Street, London, W.1.—We are, etc.,

NOEL HARRIS,
Chairman, Medical Committee.
ETHEL DUKES,
Secretary, Medical Committee.

London, W.1.

Our net gains, then, from these "conciliatory" assurances would seem to be nil, and we are likely to lose from their possible weakening effect on some in our ranks. I am convinced that nothing short of insisting on our four cardinal points as an absolute minimum will be enough to preserve our freedom—and even those, I think, will prove to be insufficient.—I am, etc.,

Thame, Oxon.

C. H. BARBER.

A Diploma for G.P.s

SIR.—Mr. A. E. Porritt (April 10, p. 673) remarks, "The war is an underlining of the values of specialization from both prestige and the financial angles . . . to a warped perspective on the relative importance of general practice, as compared with specialization. . . . It is exceptional among recently issued applicants for resident appointments to find one in it who expresses the ultimate intention of becoming a G.P."

This tendency, which was of course in evidence long before the war, is fraught with disastrous possibilities for the future of the doctoring, and many thoughtful general practitioners are realizing that it is liable to be accelerated if and when the National Health Service comes into being. On the one hand, if hospital work is adequately paid it will be much easier to specialize and so to avoid the "drudgery of general practice" to gain a larger income than can be obtained in family practice. On the other hand, there will be no inducement for a general practitioner to rise above a certain level of mediocrity. On the contrary, the more time and trouble he gives to his cases, the fewer potential patients can he accept on his list, and the lower his income.

These scales are being heavily weighted in favour of rushed work, the doctor able to do his own lumbar punctures, bleed counts, blood sugars, capable of reading his own electrocardiograms, even of removing an appendix on occasion, will become as extinct as the dodo. The prizes will go to those with a superficial skill at diagnoses.

It seems to me very essential, if we are to preserve the best features of family practice—not only in such technical matters as I have mentioned, but, far more importantly, in an understanding of the

Constructive Scheme

SIR.—In view of the apparent impasse between our Negotiating Committee and the Ministry of Health, destructive criticism having taken place on the part of the medical profession, I consider that a constructive scheme is now called for. The following scheme is submitted to replace the medical part of the National Health Service Act:

(1) All people with salaries up to £600 per annum and their dependants should receive free general-practitioner medical service on an extension of the present national health panel service.

(2) There should be free consultant and hospital service available to all patients without financial burden who come into category (1) referred to above.

(3) A contributory insurance scheme should be inaugurated by which all people with incomes of £600-£1,200 per annum should have specialist and hospital or nursing-home treatment free from expense.

(4) The State should take over all voluntary hospitals in such districts where it is deemed desirable by the public and the board of management. (It is wrong that in a poor district the less fortunate should have less efficient treatment from their local hospital because finance cannot afford the first-class equipment available in other hospitals with larger funds at their call.)

This scheme would eliminate all the contentious points arising between the Minister of Health and medical men, and would preserve the freedom so precious to our profession.—I am, etc.,

Leicester.

FRANK T. DOLEMAN.

Committee of Those Who Accept

SIR,—I quite agree with the suggestions put forward by Dr. Edward F. Hunt (April 3, p. 660). As one who is quite prepared to work in the new Service, I do feel the B.M.A. should appoint a committee on behalf of those thousands of doctors who voted "Yes," the majority of whom are active members of the B.M.A. Besides the doctors who are already prepared to take part there are probably many waverers who at this moment are feeling a certain amount of apprehension at the request for "£100 as a first instalment."

There are many minor points to be cleared up before July 5. points such as mileage allowance and the replacement of stock and drugs used daily during surgery hours. As Dr. Hunt states, there is complete freedom of choice as to entry into the new Service, and we members of the B.M.A. feel that we have a right to be represented by a committee on a high enough level to discuss these matters of detail with the Ministry.—I am, etc.,

Staines, Middlesex

HENRY BERGH.

Doctors and Dentists

SIR,—We feel that one facet of the dispute has not received sufficient notice. We mean the position of our dental colleagues. We feel that no final settlement should be agreed which is not acceptable to the dental profession too. They are as much part of the scheme as we are, and until their just demands have been fulfilled we feel the medical profession should continue to stand out.—We are, etc.,

Chippenham, Wilts

M. H. EVANS.
A. P. HICK.

Position of Assistants

SIR,—Although assistants in general practice supported their employers loyally in the plebiscite—at the same time expressing their personal disapproval of the Act in its present form—many doubts now seem to be arising in that section of the profession. The regulations outlined in the *Journal* of April 3 (p. 652) under the heading of "Medical Services in N.H.S." can only have added to their doubts by the absence of information on their present position and the possibility of succession to a practice or partnership.

The regulations appear to allow the expansion of individual practices to a possible maximum of 6,400 units in one principal's name, should that doctor employ an assistant. The capitation fees on the extra 2,400 patients far exceed the assistant's salary (one-third of that number would cover the average present rate), and with such an inflated list personal attention from the principal, which is what the patient "signed on" for, is not possible. One appears to be forced to the conclusion that such expansion is undertaken purely for financial gain and not for better service. To add to this financial advantage a "supervision fee for training an assistant" seems quite unnecessary. I fully agree that newly qualified doctors require guidance during their introduction to general practice, but to continue the system whereby a succession of assistants may be hired to boost the principal's income is commercialized medicine at its worst.

In most practices assistants build up a certain goodwill by their own merit, and should the purchase of practices be abolished it would seem reasonable to allow them to take patients in their own names from the introduction of the new scheme. The profession fears that there may be some quiet drifting into the Bevan net, and while the assistants' position remains vague and largely unrepresented it would seem that this is the quarter from which—even if reluctantly—the drift is most likely to begin.—I am, etc.,

Birmingham

JOHN GEMMELL.

Benefits for Doctors' Wives

SIR,—I note with interest the letter from Mrs. Irene Hartley (April 3, p. 661) in which she fears she will have extra work to do when the National Health Service Act comes in because records will have to be kept of all consultations and treatments. I must say I find this argument quite incomprehensible. When the N.H.S. is enforced she will be relieved of all dispensing duties and the task of sending out and collecting bills. The

keeping of records will, like the panel records to-day, surely be her husband's job. I feel that she does not fully appreciate the tremendous importance of this matter of record keeping. Locums and assistants are frequently accused by principals of making mistakes, and losing patients, but is this surprising? One considers that in most practices they have no records at all. Soever of the previous illnesses of private or club patients I feel sure that a great many errors in diagnosis and treatment could be avoided by keeping proper records for all patients. Even the best of memories are not infallible.—I am, etc.,

Wolsanton, Staffs.

ANNE M. TOWN.

POINTS FROM LETTERS

White Bread and Peptic Ulcer

Dr. G. W. LLOYD (Thornton Heath, Surrey) writes: Peptic ulcers are found in eaters of much white bread, such as men who eat sandwiches for their midday meal. These admit they eat a lot of bread, and if one counts the number of rounds they eat in a day it is found they eat much more than the average. Eaters of wholemeal bread seem free from peptic ulcer—I have not met one. Peptic ulcers heal rapidly when on the restricted diet enforced after haemorrhage or perforation, and this restriction includes a complete abstention from bread in the early days and only a small proportion of it for some weeks. . . .

Since Sir Edward Mellanby's preliminary notice in the *BMJ* in the autumn of 1946 that white bread caused hysteria in the full pressure has been put on all cases. They have been told it would be well if they kept to wholemeal bread and promised return of symptoms if they ate white bread. The result has been a cessation of symptoms, relief from pain coming before complete healing is possible. Temporary failures have been caused by (1) eating of white flour, pastries, and cakes (one case); (2) return to white bread in a few cases because of preference—these require correction but the majority found conviction; (3) adulteration of wholemeal bread by white flour by some bakers. (This adulteration is shown by blotches of white in the general brown colour of wholemeal bread.)

Pain in Coronary Occlusion

Dr. W. H. MYERS (London, S.E.9) writes: I was called to see a case recently and witnessed the events preceding a fatal acute coronary occlusion—an event which is usually so sudden that the practitioner finds the patient has died before help or even examination is possible.

The patient was a man aged 69. He had been in pain for two hours and told me it was severe—as if there was a band in his chest preventing him from breathing. He said he felt the severe pain in the upper part of the right chest and right arm, leading question about his left arm made him assert that there was some pain there, but he continued to rub his right arm, particularly the inner side of it. While I was examining him his condition became worse and the pain more severe. The capillary refill was so prolonged that I did not see any colour in his forearm. I gave him an intravenous injection of morphine sulphate (16 mg.), atropine sulphate gr. 1/100 (0.65 mg.), and aminophylline 10 ml., slowly. The effect was dramatic. His voice failed, he uttered a blurred mumble, the eyes closed, and he apparently slept. A few minutes later the pain began to break through again, and he died in half-an-hour. At post-mortem examination the cause of death was found to be atheroma of the coronary arteries, moderate degeneration, and cardiac failure.

The unusual point of the case was the insistence of the patient that the pain was right-sided and radiated down the right arm, whereas most books suggest the radiation is left-sided.

Natural Position for Childbirth

Dr. MARY KEITH-THOMPSON (Manchester) writes: During the early part of my domiciliary midwifery practice in Northern Lancashire I came across some articles on the subject by Dr. Kathleen V. Now the squatting position is the position in which a Hindu lady usually answers to the calls of Nature. So I tried to tell them in the vernacular to sit as though they were sitting on a toilet.

My midwife assistant would put clean newspapers on the floor, place a foot apart, and a sterile sheet or towel on the floor. As soon as the head was visible the patient would be placed on the bed and delivered, in the usual position. Sometimes the patient preferred to squat on the bed. Of course this is by no means a comfortable position for a patient at full term, and she flatly refused to squat. . . .

General anaesthetics—necessary in forceps deliveries—are regarded with fear and trembling in domiciliary obstetrics. Therefore in slight disproportions this form of delivery is extremely useful.

kly Heat

r. JAMES H. SEQUEIRA (N'Gong, Kenya) writes: The correspondents who have written to you on this subject do not appear to be acquainted with the work of the late Dr. E. C. Smith, of 25. In his *Atlas of Skin Diseases in the Tropics* (Bale, Sons and Ielsson, 1932) he describes *monilia* which are found in the roofs of the vesicles which are a special feature of prickly heat. The nism has a well-developed mycelium and clusters of spores.

Dr. Smith grew the organism on Sabouraud's medium, and the cultures reproduced in volunteers the phenomenon of kly heat. . . . His research would appear to settle the question of aetiology of the affection. Warmth and moisture and probably a ble pH would provide a favourable medium for the growth of parasite, which may develop in the alimentary tract. His work l also explain the efficacy of treatment by powerful fungicides as the strong sublimate lotion (perchloride of mercury, 1 in 1) advocated by Dr. C. J. Wilson in the *Journal* of Jan. 10 76).

ny Wife

Dr. D. F. A. NEILSON (London, W.1) writes: A few days ago as listening to the commentator of a British news-reel describing telephone gadget by means of which doctors would be able to e a phonograph record made of incoming telephone messages ch were passed at a time when the telephone at their office or se might be unattended. It was described as being suitable for octor without a wife or a secretary. This epitomizes the opinion the lay public or official mind as to the "duties" of a doctor's .

ctors' Wives

rs. IRIS BROOK (London, S.E.9) writes: I would like to point to these misguided doctors' wives who are wasting their time money by joining the League of Doctors' Wives that if their bands join the Health Service a rota of duties can be arranged, rebly giving each doctor and his wife regular relief from routine ies. The present competitive system is not conducive to "good lieine." The fear of another doctor taking a patient is too often reason for single-handed practitioners being tied to their teleones or door bells. . . . As a doctor's wife of over 20 years' iding I think I know the snags and difficulties which are the lot a doctor's wife, but we were not "directed"; we chose husband's s and all entirely of our own volition. The shortage of man- woman-power is a national problem, and it would be interesting know the labour pool from which Mrs. Hartley suggests the ister of Health should direct the domestic and secretarial help every doctor entering the new service. Apart from the economics uch a scheme, there might be some objections by the "directees."

* This correspondence is now closed.—Ed., B.M.J.

w Act

Dr. A. VICTOR RUSSELL (Wolverhampton) writes: Remember that present Government, with its enormous majority, on the day r we entered the Service on the terms suggested by Lord Moran d introduce a small Bill designed to convert us into a whole- e salaried State service (and do not forget that this is still official ialist policy), and in spite of any opposition that could be offered it through all its stages in a matter of weeks or even days. us make it perfectly plain that we are not prepared to fall for olitical trick of that sort. . . . n conclusion, I should like to ask a question. Should the vernment concede all our principles, we are at the moment com- ted to entering their Service; but even assuming such wholesale ecession would there not still be chaos on the "vesting day"? there would not be one extra hospital bed, one single extra se, or any more equipment available than there is at present? is time that we thought about this and put forward a demand any new service to be introduced by stages—by evolution and y revolution. In fact, if we are wise we should stand out a completely new Act.

sonal Freedoms

Dr. ARTHUR E. CLAYTON (Dorington, Salop) writes: I believe at bottom the profession is fighting for the elemental personal free- ne of every man, woman, and child in this country, to say nothing those who come after us, and that we form a small but important or in that great front which is being mobilized not only in repute but over the world in defence of these absolute values which e any meaning to life at all. If this be so, herein is the nourish- nt for our "morale" and a clear-cut vision of where we stand we view ourselves in the mighty company of those being mar- tled in every country where genuine democracy is being upheld. may be said that this is rhetoric fancy and illusion. To me at t it is sober fact. We are facing dangerous possibilities, and I trust that the public mind should be raised above our professional ments about this and that and brought into that clearer atmo- here where the crucial issues can be clearly perceived.

Obituary

Mr. GEORGE POTTS died at his home in Maidstone on March 13 at the age of 71. He was born in Chester and educated at Edinburgh, where he qualified in 1900. He subsequently studied in London and Vienna, and took the F.R.C.S.Ed. in 1906. He went to Maidstone originally as a house-surgeon at the Ophthalmic and Aural Hospital after holding the appointment of registrar at the Central London Ear, Nose, and Throat Hospital. During the 1914-18 war he served with the R.A.M.C. and was with the Black Watch in India and the Middle East. After the war he returned to private practice in Maidstone, and was appointed honorary surgeon to the hospital there. He had consulting-rooms in London, and was also one of the ophthalmic specialists for the Ministry of Pensions. Mr. Potts was a bachelor, and was well known as a freemason and in connexion with All Saints' Church, Maidstone.

Dr. ROBERT DOUGLAS, who was medical officer of health for Moray and Nairn for over thirty years, died in the Aberdeen Royal Infirmary on March 19 at the age of 76. Robert Douglas was educated at Dallas Public School and Elgin Academy, and subsequently at Aberdeen University, where he graduated M.A. in 1893. He then went on to study medicine at Glasgow, and graduated M.B., Ch.B. in 1898. He soon became interested in public health, and particularly in school health administration, and his first public health post was as assistant medical officer of health at Reading. He took the D.P.H. at St. Andrew's in 1906 and proceeded M.D. in 1914. He became school medical officer for the Norfolk County Council and later for the West Riding County Council of Yorkshire. In 1911 he succeeded as medical officer of health for the County of Moray Dr. James A. Cameron, who continued as medical officer of health for Nairnshire. When Dr. Cameron resigned in 1918 Dr. Douglas also succeeded him at Nairn. He was, too, M.O.H. for the burghs of Grantown-on-Spey, Forres, and Burchard, and on the death of Dr. A. Robertson, of Elgin, in 1941 he also became responsible for Elgin, Lossiemouth, and Rothes. This placed him in the unusual position of being responsible on the public health side for three counties and seven burghs. Apart from his official duties, his chief interest was in local history, on which subject he was an authority. His best-known work was the *Annals of Forres*, which was published privately in 1935, but he was also the author of many booklets and articles on local matters. On the occasion of his retirement towards the end of 1941 he was presented with a cheque by a deputation from the Joint County Council Dr. Douglas is survived by two sons.

Dr. ALISON MARY HUNTER, who died on March 26, was educated at the University of Glasgow, graduating M.B., Ch.B. in 1918. She was associated with the Glasgow Royal Infirmary for over twenty years, and was also the senior gynaecologist and obstetrician at the Redlands Hospital for Women, Glasgow. She was honorary consulting gynaecologist to the Glasgow Royal Mental Hospital, and she had been the late Prof. James Hendry's assistant for a number of years before being elected F.R.C.O.G. in 1939. She succeeded Prof. Hendry as gynaecological surgeon to the Royal Infirmary in October, 1946. She was a former chairman of the Glasgow branch of the National Vigilance Society, and at the time of her death was treasurer of the Medical Women's Federation.

Dr. ROBERT MICHAEL FORDE, who died at his home in Worthing on March 27 at the age of 87, after a long illness, had spent many years in the West African medical service. Dr. Forde was a student of Queen's College, Cork, and qualified in 1885. He served in West Africa for over twenty-five years, his last post being that of P.M.O., West African Medical Staff, at Sierra Leone. He retired in 1914 and served in the R.A.M.C. with the rank of major. He was responsible for some of the early work in Gambia on trypanosomes. Dr. Forde had been an invalid for the last four years and he leaves a widow and one son.

Dr. KEITH ANTONY REGINALD HENRY died at the age of 25 on April 1. Dr. Henry was born at Birkenhead and received his early education at Lytham and at Arnold School, Blackpool. He graduated M.B., Ch.B. at Edinburgh University in December, 1945, and was engaged for some time as a locum-tenent in the Manchester and Blackpool areas of Lancashire. He had recently taken up an appointment as District

Medical Notes in Parliament

CRIMINAL JUSTICE BILL

On April 14, when the Criminal Justice Bill was considered on Report, Mr. SYDNEY SILVERMAN moved a new clause suspending for five years the sentence of death for murder and substituting imprisonment for life. Mr. HOLLIS seconded the Motion.

Mr. Hollis remarked that Mr. Bernard Shaw argued that certain murderers could be reformed, but said that doctors could certify that other people were beyond reformation and should be killed "as one would kill a mad dog." Mr. Hollis commented that Mr. Shaw had never previously expressed the smallest regard for any opinion expressed by a doctor and would not admit that a doctor was capable of telling him whether he should be vaccinated. Mr. Hollis reminded Members that the greatest of living psychologists, Dr. Jung, was of opinion that on the whole capital punishment was a slight encouragement to murder rather than a deterrent. People with perverted tendencies got an extra thrill out of feeling that in their war with society they contended for the highest of all stakes. Under the present system the criminal was offered all the thrills of risking his life and comparatively little of the danger of losing it.

Sir JOHN ANDERSON thought in what was called "constructive murder," where a person on "some felonious enterprise unwittingly caused death, the death penalty had no deterrent effect, and he doubted whether it had any in what the French called *crime passionnel*. Broadly, however, the death penalty did reinforce the protection of society and diminished the risk to which officers of the law were exposed. He called attention to the evidence of Sir Alexander Paterson to the effect that if the capital sentence were abolished the change should not make any difference to the present regime. Sir Alexander thought that ten years was a sufficient period of detention, and he thought that after that time physical and mental deterioration set in. Parliament could not get out of the difficulty by saying that prisoners who were morose and subject to gusts of passion ought to be certified insane. Lord Atkin had tried to get what were called the M'Naghten Rules extended to cover cases of murders committed by persons suffering by reason of some defect of mind from what was called ungovernable impulse, but his recommendations had not been accepted.

Mr. HALE said the unanimous testimony of governors of prisons, including the governor of Pentonville, was that the effect on the prison population of an execution was disastrous. The men suffered neurosis and moral horror intensified by their imprisonment. If the condemned man slept on the night before his execution he was usually the only person in the prison who did so.

Mr. WILSON HARRIS remarked that in 1937, 87 people died by murder and in the same year 6,633 were killed on the roads of this country. In 1947 in England and Wales there were 27 executions; in 1946 there were 30.

Mr. CHUTER EDE did not believe that public opinion in this country was in favour of the clause at this time. The rules for the granting of reprieves had been fairly applied by successive Home Secretaries. There had been no answer during the debate to the argument that, if the death penalty were abolished and a prison sentence substituted which public opinion would tolerate, it would become impossible to conduct the present service on the lines that Sir Alexander Paterson desired.

The new clause was carried by 245 to 222 and was added to the Bill.

Payment of Medical Witnesses

The Criminal Justice Bill was again considered on April 15.

On Clause 24, on remand for inquiry into the physical or mental condition, Mr. YOUNGER moved amendments relating to the payment of allowances to medical practitioners who attended a court to give evidence. These amendments were designed to ensure that allowances should be payable only when the witnesses actually attended and did not merely give evidence by means of a report. The amendments were accepted. Subsequently Mr. EDE moved a further amendment to Clause 22 to make similar provision regarding the payment of witnesses' allowances to medical practitioners who gave evidence under Clause 22 in a case where an offence was not indictable and was made under Clause 24. Mr. Ede said Clause 22 as it stood did not provide for payment of allowances to medical practitioners in such a case and it was highly desirable that there should be power to make such payment.

On Clause 4, which concerns probation orders requiring treatment for a mental condition, the Speaker declined to call an amendment by Mr. JAMES HUDSON instructing the court to

consider whether a condition of abstinence from drugs, intoxicating liquor should be attached to the probation order.

Mr. EDE moved amendments to make certain that the medical practitioner who is consulted about the mental state of an offender shall be one who is competent to guide the court. He proposed, after the word "practitioner," to insert "and to the court to be experienced in the diagnosis of mental disorders." It would be the duty of the courts to make themselves reasonably acquainted with the qualifications of the medical practitioners concerned.

Mr. JANNER said that Members who had fears about the use of medical men who would be consulted felt bound to say Mr. Ede had gone as far as he could to satisfy those fears. He hoped that Mr. Ede would later allow another medical practitioner also to be consulted. The amendment was carried as was also one proposed by Mr. YOUNGER that a report on the mental condition of a prisoner could be received in evidence without proof of the signature, qualifications, or experience of the practitioner signing it.

Mr. EDE moved to modify Clause 33 to exempt children under 14 years from this provision, and to make clear that before a court could order finger-prints to be taken a person over 14 years of age must have been taken into custody, or have been charged with an offence, and the court must consider that this was a case in which this power should be given to the police. These amendments were agreed to.

Radioactive Substances Bill

A Radioactive Substances Bill has been introduced by the Government in the House of Lords. The object of this Bill is to enable various Ministers of the Crown to make regulations controlling the manufacture, storage, supply, and use of radioactive substances, which are defined as substances "which consist of or contain any radioactive chemical element, whether natural or artificial." Only doctors and dentists, or persons acting under their direction, are to be permitted to use "irradiating apparatus" for therapeutic purposes. The health of those who have to work with radioactive substances is to be safeguarded by appropriate regulations, and steps are to be taken to ensure the safe disposal of radioactive waste products. Ministers concerned must consult an Advisory Committee which will be set up for the purpose, about the exercise of any of their functions under this Bill.

Health Centres

Mr. PLATTS-MILLS reported on April 15 that widespread anxiety had been aroused by a recent circular to local authorities discouraging any development of health centres at present time; he asked Mr. Bevan to issue further instructions making it clear that it was not his intention to discourage any initiative in the planning and setting up of new health centres.

Mr. BEVAN said there was evidently a misunderstanding. He had never wished to discourage health centres, which would be a key feature of the new Health Service. But he had pointed out the building stringencies of the moment and said that he did not, therefore, expect any widespread programme.

Grants for Postgraduate Training

On April 15 Group Captain WILCOCK asserted that a number of trained medical specialists in receipt of Government grants would terminate their appointments at hospitals before their appointed day. He asked what Mr. Bevan proposed to do to the continuation of these grants until appointments were made under the new Act.

Mr. BEVAN, in his answer, assumed that the question related to appointments under the scheme for postgraduate education for doctors released from the Forces, now held by practitioners who before joining the Forces were training to become specialists and desired to continue their training. These practitioners would continue under the National Health Service. Some of the practitioners concerned were, on account of their special circumstances, receiving grants under the Government's Education and Training Scheme. These also would continue.

Transfer of Medical Officers of Health

Mr. LIPSON on April 15 asked Mr. Bevan to postulate the transfer to county councils of medical officers of health from their staffs and offices from the new "most purposes" boroughs recommended by the Boundary Commission. A decision had been made with regard to implementing part of their report.

Mr. BEVAN replied that any transfers of staff and premises essential to transferred functions under present legislation would be made if county councils were to carry out the decision. He had given them from the appointed day.

Dr. Atso Soivio, Finnish Red Cross Hospital plastic surgeon, is in Britain until the middle of May under the auspices of the British Council. He specializes in the treatment of cleft palate and hare-lip, including speech therapy, and is here to meet British plastic surgeons and study operations.

No. 14

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended April 3.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland. *Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for:* (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland. A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

|| Includes puerperal fever for England and Wales and Eire.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In *England and Wales* an increase was recorded in the incidence of measles 1,566, acute pneumonia 44, whooping-cough 36, and dysentery 52. There was a decrease in the notifications of scarlet fever 105.

The increased incidence of measles was concentrated in London and the surrounding counties; the largest rises were in London 294, Middlesex 194, Essex 142, Kent 129, Durham 11, Lancashire 105, and Surrey 91. Changes in the local trend of whooping-cough occurred in only a few counties; the largest were increases in Sussex 52 and Kent 35 and a decrease in Yorkshire West Riding 62.

The chief feature of the returns for diphtheria was a fall of 10 in London. The only fluctuation of any size in the incidence of scarlet fever was a decrease of 33 in Yorkshire West Riding. Only small variations occurred in the returns of acute pneumonia.

A fresh outbreak of dysentery involving 28 persons was notified in Cardiff C.B. Increases were recorded in the notifications of dysentery in Lancashire from 59 to 80 (Liverpool C.B. 24, Oldham C.B. 27) and in Yorkshire West Riding from 18 to 35 (Todmorden M.B. 15). The only other large return was London 14.

The fall in the notifications of acute poliomyelitis continued. The only administrative areas with more than one case were Lancashire, Liverpool C.B. 2, and Somerset, Bridgwater M.B. 2.

In *Scotland* there were rises in the incidence of scarlet fever 44, acute primary pneumonia 37, and cerebrospinal fever 7, and decreases were recorded for measles 74, whooping-cough 15, and dysentery 15. The increases in the notifications of cerebrospinal fever and scarlet fever were mainly due to the expansion of the city of Glasgow. Although the notifications of diphtheria remained unchanged for the whole country an increase of 13 was recorded in Glasgow.

In *Eire* increases were recorded in the returns for scarlet fever 10, whooping-cough 7, and diarrhoea and enteritis 5. There was a decrease of 9 in the notifications of measles.

In *Northern Ireland* only small changes were reported in the trends of infectious diseases.

Information for Travellers

Greece.—The following ports have been reopened to arrivals from Egypt: Piraeus, Salonika, Patras, Volo, Cavalla, Alexandropolis, Canea, Heraklion, Rhodes, Samos, Mytilene, Kalamae, and Corfu. Vaccination and surveillance are the sole measures remaining in force.

Hong Kong.—All passengers are required to produce certificates showing that they have been vaccinated against smallpox not more than three years before departure from an infected port. The certificate should show that the result of the vaccination has been observed and recorded in one of the following terms, viz.: (a) immediate reaction, reaction of immunity, immune; (b) accelerated reaction or vaccinoid; or (c) type primary vaccinia or vaccinia. A certificate of "unobserved" or "no reaction" will not be accepted. The certificate should also bear a photograph of the holder embossed or stamped with an official seal, and be signed by a medical or health officer occupying an official position in the services of a Government or Municipal Health Department.

Shanghai.—All passengers and crew disembarking at Shanghai are subject to medical inspection and are required to produce valid certificates of vaccination against smallpox not more than twelve months old, failing which they will be vaccinated if necessary, detained for surveillance.

Singapore and Federation of Malaya.—Requirements: (a) Medical inspection. (b) Vaccination certificate (International Model) not more than three years old and containing in the certificate a note of the type of reaction observed and including the dates of vaccination and observation results. The certificate is to be signed by a medical officer occupying an official position in the Government or Municipal Health Department. (c) Vaccination, possession of certificate, and surveillance up to a period of fourteen days after the arrival of the ship. (The above requirements apply to cabin passengers who are not contacts. In the case of other passengers observation is required at the Quarantine Station.)

Infectious Diseases During the First Quarter

The trends of the infectious diseases during the first quarter of this year show some interesting contrasts with previous years. The most notable of these comparisons is the entire absence of an influenza epidemic. The deaths from influenza in the large towns were about one-sixteenth of those recorded in the first quarter of 1940, the last year in which

dence. The downward trend of diphtheria continued, and notifications were the lowest recorded in a first quarter. Notifications of acute pneumonia were very low. The incidence of cerebrospinal fever declined after remaining practically constant for five years at about three times the pre-war level. Whooping-cough was unusually prevalent during this quarter. Measles was at an exceptionally high level for an inter-epidemic period.

Scarlet fever was also very prevalent. The number of notifications for the first quarters of the last five years were:

England and Wales	1944	1945	1946	1947	1948
Scarlet fever	26,962	19,163	16,952	15,527	23,348
Whooping-cough	26,141	19,780	20,033	27,922	35,034
Diphtheria	9,005	6,061	6,220	2,832	2,466
Acute pneumonia	20,278	247,435	17,652	165,895	88,489
Cerebrospinal fever	14,977	14,782	16,278	15,500	10,969
Dysentery	978	968	906	1,110	629
Enteric (typhoid and paratyphoid)	2,834	4,681	4,444	931	2,100
Enteric (typhoid and paratyphoid) in towns	111	140	138	98	103
Deaths from influenza	1,131	692	2,156	1,341	273

Week Ending April 10

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,196, whooping-cough 13, diphtheria 155, measles 11,193, acute pneumonia 703, cerebrospinal fever 36, acute poliomyelitis 14, dysentery 111, enteric 3, and typhoid 7.

Medical News

Awards for Cancer Research

Prof. Alexander Haddow and Prof. Eric Boyland have been awarded the Katherine Berkan Judd Award by the Memorial Hospital, New York. They are both in New York receiving the award, which is for outstanding contributions to elucidating the causes and treatment of cancer. Prof. Haddow is the Director of the Chester Beatty Cancer Institute at the Royal Cancer Hospital and Professor of Experimental Pathology in the University of London. He has worked on chemical carcinogens and growth inhibitors. Prof. Boyland is Professor of Biochemistry in the University of London.

Director-General of F.A.O.

Mr. Norris E. Dodd, United States Under-Secretary of Agriculture, has been elected Director-General of the Food and Agriculture Organization in succession to Sir John Boyd Orr.

National Midwives Board

At its April meeting the Central Midwives Board re-elected Mr. Arnold Walker, F.R.C.S., F.R.C.O.G., as chairman and Mr. J. P. Hedley, F.R.C.P., F.R.C.S., F.R.C.O.G., as vice-chairman for the ensuing year.

Pathology Service

A pathology service has been established for Portsmouth and Isle of Wight, the senior pathologist and adviser being Dr. E. M. Darmady. Dr. Radcliffe has been appointed pathologist. Dr. Dobson assistant pathologist. It is hoped to appoint other assistant pathologist and biochemist. The scheme is being financed by the Royal Portsmouth Hospital and includes all the hospitals of Portsmouth as well as the Royal Isle of Wight County Hospital, Ryde. The Ministry of Health has given permission to convert a building in the Portsmouth Isolation Hospital to house a bacteriology under the Public Health Service, and it is hoped that it will also undertake the hospital bacteriology.

Rockefeller Foundation

The Rockefeller Foundation is giving a donation of £9,000 for research at the Neuropsychiatric Research Centre at Whitechurch Hospital, Cardiff. The grant is designated "for research in normal pathological biochemistry of brain tissue under the direction of Dr. Derek Richter." The object of the research now being carried out in the Research Centre at Cardiff is to discover more about the working of the central nervous system in health and disease, so that this knowledge can be applied to the treatment of mental disorders. The lines of research now in progress include chemical work on the enzymes in the brain and work with radioactive tracers. Clinical research is also being carried out on problems related to schizophrenia, epilepsy, and senility.

Dr. Bernard Henry Spillbury, the former Home Office pathologist, £9,232; Dr. Herbert Stanley Jones, of Southampton, £548; Dr. Charles Veatch Knight, of Paiswick, Glas., £64,090; Dr. Henry Orr, of London, S.W.4, £25,485; and Dr. Robert Scott, of Peterborough, £24,591.

COMING EVENTS

University of Durham, Department of Surgery

Sir Heneage Ogilvie will give the third Rutherford Morrison Lecture in the Royal Victoria Infirmary, Newcastle-upon-Tyne, on Wednesday, May 5, at 5 p.m. His subject is "A Surgeon's Life."

Lecture on Laryngectomy

Dr. Jean Leroux-Robert, of Paris, will deliver a lecture on "A Modification of Laryngectomy" at the Institute of Laryngology and Otology, 330-332, Gray's Inn Road, London, W.C., on Thursday, May 6, at 3 p.m. His address will be illustrated by a cinematograph film.

N.A.P.T. Medico-Social Section

The Inaugural Meeting of the N.A.P.T. Medico-Social Section will be held on May 7 at 5 p.m. at B.M.A. House, Tavistock Square, London, W.C.1. Sir Robert Arthur Young, Vice-Chairman of Council of the N.A.P.T., will preside, and Dr. Norman Lloyd Rusby, Assistant Physician, London Hospital, and London Chest Hospital, will address the meeting on "Social Aspects of Tuberculosis." The Section is open to members of the N.A.P.T. who are professionally engaged on social work for the tuberculous, and whose names are approved for Section membership by the committee of the Section, but an invitation to the Inaugural Meeting is extended to all who are interested in this work.

Biological Standards

A meeting of the Biological Methods Group of the Society of Public Analysts and Other Analytical Chemists will be held at the Chemical Society's Rooms, Burlington House, Piccadilly, London, W., on Tuesday, May 11, at 6.30 p.m., when Dr. A. A. Miles, Head of the Standards Department of the National Institute for Medical Research, will read a paper on "Biological Standards." Visitors are welcomed at the meetings of the group and may take part in the discussion following papers.

Gastro-enterology in U.S.A.

The National Gastroenterological Association will hold its 13th Scientific Session at the Hotel Pennsylvania in New York City on June 7-10. Further details may be obtained from the Secretary of the Association, 1819, Broadway, New York, 23.

Conference in Brussels

A conference, including clinical demonstrations, will be held at Brussels on June 12-16. The National League against Tuberculosis will meet as well as the Association of Dentists of Belgium and the Belgian Society of Physical Education and Sport. Information may be obtained from Dr. L. Mayer, Faculté de Médecine, Rue de la Gendarmerie, Brussels.

SOCIETIES AND LECTURES

Monday

EDINBURGH UNIVERSITY: PHYSIOLOGY CLASSROOM.—April 26, 5 p.m. "Medicine and the Classics," by Dr. Douglas Guthrie. ROYAL SOCIETY OF ARTS, John Adam Street, Adelphi, London, W.C.—April 26, 4.30 p.m. Third Cantor Lecture on Recent Advances in Anaesthesia. "Endotracheal Anaesthesia—Local, Regional, and Spinal Anaesthesia—Intravenous Anaesthesia—Rectal Basal Narcosis—Curare—Combination or Balanced Anaesthesia—The Old and the New," by Dr. Francis T. Evans.

Tuesday

INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY, 330, Gray's Inn Road, London, W.C.—April 27, 4.30 p.m. "The Surgical Treatment of Deafness," by Mr. Terence Cawthorne. UNIVERSITY COLLEGE LONDON: DEPARTMENT OF PHYSIOLOGY.—At Physiology Theatre, Gower Street, London, W.C.—April 27, 5 p.m. "Speech as the Communication of Ideas: The Sequence of Events in Speech: The Psychological Aspect of Speech," by Mr. D. B. Fry, Ph.D.

Wednesday

SOCIETY OF CHEMICAL INDUSTRY: FOOD GROUP.—At Burlington House, Piccadilly, London, W., April 28, 6.30 p.m. 17th Annual general meeting. "On the Chemistry of Coffee," by Dr. E. B. Hughes.

Thursday

EDINBURGH ROYAL INFIRMARY.—April 29, 4.30 p.m. Honyman Gillespie Lecture: "Arterial Embolism," by Prof. J. R. Learmonth.

Friday

KENT AND CANTERBURY HOSPITAL, Canterbury.—April 30, 8 p.m. Monthly clinical meeting. SURREY COUNTY MEDICAL SOCIETY.—At Redhill County Hospital, April 30, 6.30 p.m. Clinical meeting.

APPOINTMENTS

Dr. Jules Maurice Curé has been appointed a Member of the Executive Council of the Colony of Mauritius.

H. H. Cavendish Fuller, M.B., has been appointed Chief Medical Consultant to the Railway Executive.

Dr. Cavendish Fuller qualified at Edinburgh in 1912 and obtained the M.D. in 1931. He is at present chief medical officer to the Western Region at Paddington Station and will continue his duties for that region while acting as consultant to the Railway Executive.

David Harley, M.D., Allergist to Moorfields Westminster and Central Eye Hospital.

Dr. Harley works in the Inoculation Department of the Royal Institute of Medicine and Legation, London.

Mr. W. G. Senior, O.B.E., L.D.S., has been appointed to succeed Mr. H. A. Mahony, L.D.S., as Principal Dental Officer of the Ministry of Health.

Mr. Senior was appointed to the Ministry in 1947 as senior dental officer and had previously been dental secretary of the British Dental Association since 1931.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Edwards.—On April 8, 1948, at Abingdon Hospital, to Judy (née Wilkin), wife of Flight Lieutenant Jack Edwards, R.A.F.V.R., a daughter—Susan Mary.

Fenn.—On April 8, 1948, at Bullh Wells Cottage Hospital, Breconshire, to Betty, wife of Dr. C. M. Fenn, "Cerdyn," Llanwryd Wells, a daughter—Lynda Elizabeth.

Jarvis.—On April 12, 1948, at Queen Charlotte's Hospital, Hammersmith, to Anne, wife of Dr. H. Jarvis, 236, Park Street, Luton, Beds, a daughter—Ruth Sandra.

Valentine.—On March 26, 1948, at 31 (British) General Hospital, Austria, to Constance, wife of Major G. F. Valentine, R.A.M.C., a daughter—Diana St. Clair Fotheringham.

MARRIAGES

Blair—Gilbert.—On April 10, 1948, at Ness Bank Church, Inverness, Dr. Robert Alexander Blair, son of Mrs. A. L. S. Blair, 3, Elliot Place, Edinburgh, and of the late Mr. R. A. Blair, F.M.S., to Dr. May Lois Gilbert, younger daughter of Mr. and Mrs. Robert Gilbert, Belle Vue, Inverness.

Denlon—Moore.—On April 5, 1948, at St. Peter's, Vere Street, London, W., Mervyn Denlon, M.R.C.S., L.R.C.P., D.A., to Willow Gwennap Moore.

DEATHS

Creagh.—Recently, at Folkestone, Percy Nagle Creagh, L.R.C.P.&S.I. & L.M., late Deputy Commissioner of Medical Services, Ministry of Pensions.

Crompton.—On April 6, 1948, at Mayfield, Hyde Road, Gorton, Manchester, Ralph Johnson Crompton, F.R.C.S.Ed.

Davies.—On April 2, 1948, at Bedford Lodge, Whyteleafe, Surrey, Herbert Rees Davies, M.D.

Edwards.—On April 16, 1948, George Vernon Edwards, L.R.C.P.&S.Ed., L.R.F.P.S.Glas., of West Clondan, near Guildford, Surrey, aged 82.

Fisher.—On April 11, 1948, the result of an accident, Nina, the wife of R. H. W. Fisher, M.R.C.S., D.P.H., 28, Cecil Street, Lytham, Lancs, daughter of the late Dr. Washington Epps.

Frankel.—On April 10, 1948, at Colindale Hospital, London, N.W., Peter Frankel, M.D., aged 33.

Goldie.—On April 6, 1948, Eric Avery Gordon Goldie, M.B., B.Chir., A.F.C., of 190, Sheen Road, Richmond.

Hancock.—On April 11, 1948, at Stoke-on-Trent, Arthur Hancock, M.B., Ch.B.

Henry.—On April 1, 1948, Keith Anthony Reginald Henry, M.B., Ch.B.Ed., aged 25.

Houghton.—On April 6, 1948, at Lyndene, Berkhamstead, Herts, Leonard Frank Houghton, M.R.C.S., L.R.C.P.

Jones.—On April 8, 1948, at General Hospital, Aberystwyth, David William Fenwick Jones, M.B., B.S.

Kendall.—Recently, Ernest Robert Kendall, M.S., of 7, Chester Crescent, Newcastle, aged 79.

Langstaff.—On April 12, 1948, James William Langstaff, D.S.O., L.R.C.P.&S.I. and L.M., Colonel, late R.A.M.C.

Latham.—On April 4, 1948, at Brig-y-don, Llanaber, Barmouth, Arthur William Latham, M.D., late of St. Helens, aged 74.

Lawrie.—On April 1, 1948, at Edinburgh, Thomas Harcourt Lawrie, L.R.C.P., &S.Ed., late of Polmont.

MacDougall.—On April 4, 1948, at 28, Manchester Road, Southport, Donald Kerr MacDougall, M.B., Ch.B.

McInosh.—On April 5, 1948, at 35, Carlton Place, Aberdeen, James McInosh, M.D., LL.D., Professor of Pathology in University of London at Middlesex Hospital, London, W.

May.—On April 2, 1948, at Godders, Botley, Hants, Henry James May, M.B., B.Ch., aged 50.

Morment.—On April 16, 1948, at Royal Naval Hospital, Chatham, Robert Harry Morment, O.B.E., M.R.C.S., L.R.C.P., Surgeon Rear-Admiral, R.N., retired, aged 74.

Packham.—On March 31, 1948, George Packham, M.R.C.S., L.R.C.P., of The Drive, Barmouth.

Robb.—On April 3, 1948, at Charlestown, Duddingston, Edinburgh, Archibald Patterson Robb, L.R.C.P.&S.Ed.

Robertson.—On April 17, 1948, at 55, Upper Parliament Street, Liverpool, John Walter Robertson, L.R.C.P.&S.Ed., L.R.F.P.S.Glas.

Sherratt.—On April 9, 1948, at Bulawayo, Southern Rhodesia, Arnold Heston Sherratt, M.C., M.D., D.P.H.

Smith.—On April 18, 1948, at Guy's Hospital, London, S.E., David Murray Smith, M.B., B.Ch., of 56, North End House, London, W., aged 28.

Tyler.—On April 18, 1948, at Cratcliffe, Rotherham, Rotherham, George Nelson Tyler, M.B., B.Ch., aged 28.

Any Questions?

Correspondents should give their names and addresses (for publication) and include all relevant details in their questions which should be typed. We publish here a selection of questions and answers which seem to be of general interest.

Food Value of Honey

Q.—What are the nutritive properties of honey, and is any truth in the assertion that it promotes the formation of haemoglobin?

A.—Natural foodstuffs are so variable in composition that age figures may be misleading. However, according to V.L. Charley (*Chemistry and Industry*, 1947, p. 271) the following is an "average analysis" of honey: moisture 17.7%; sugar 75.0%; sucrose 2.0%; dextrin 1.5%; ash 0.18%; traces of pollen, wax, and nitrogenous matter. Other authorities give figures over a range as follows: water 8-25%; glucose 30-42%; fructose 23-39%. The sugars in honey are not absorbed and, with the exception of the small amount of sucrose, require no preliminary hydrolysis in the small intestine. Unlike starchy foods, honey does not give rise to gas in the intestine. It can be used in diets in place of glucose and cane sugar, and is preferable to the former as it is more palatable. It has been used in infant feeding, but it is slightly laxative. The statement that honey promotes the formation of haemoglobin can have no foundation as it contains none of the known haemopoietic factors and only traces of iron (0.11 mg. per ounce). Generally speaking, honey should not be regarded solely as a source, and a very attractive one, of calories. Honey is never adulterated with cane sugar, which would ruin the taste. It is often blended with invert sugar, though the blending must be declared on the label, for a mixture cannot legally be described as honey. There are considerable analytical difficulties in distinguishing between mixtures of honey containing moderate percentages of added invert sugar and pure honey. Certain by-products of the inversion process have sometimes been used; unfortunately, some of these appear to be able to make identical or similar products, thus making life difficult for the analyst. Blended honeys consist of honeys from several sources. Diluted honeys consist of pure honey plus invert sugar. However, it is almost certainly true that some reputable manufacturer of branded or unbranded honeys sometimes caters it with undeclared invert sugar. A wide range of figures has been recorded for the vitamin C content of honey, but usually of the order of 5 to 20 mg. ascorbic acid per 100 g. That even an unusually rich honey is unlikely to contribute to daily requirements, unless it is taken in exceptionally large quantities. Convincing evidence for the presence of riboflavin, or nicotinic acid in honey, at any rate in the amounts, is not available. A solitary reference to the presence of "vitamin A" in honeycomb does not justify our regarding honey as a source of the vitamin, for it is not clear whether the reference is to vitamin A or to a carotenoid, and if the latter the more likely, to the latter whether to a true vitamin or not; nor is there any distinction drawn between the comb and the honey. There appears to be no record of the presence of β -carotene in honey as such. Royal jelly, of course, contains considerable quantities of B vitamins and is particularly rich in riboflavin and pantoic acid.

Exercise in Middle Age

Q.—Is physical exercise desirable in middle age, or is it deleterious? What are the biochemical factors which strenuous exercise beneficial in youth but possibly harmful in later life?

A.—These questions cannot be answered completely. Bodily exertion of some kind, in greater or lesser amounts, appears to be instinctive from the moment of birth to the end of the whole of life, save in the case of the abnormal individual. In a state of nature the demand for physical exertion would be satisfied as instinctively as the demands for food, hunger, thirst, or cold. But, excluding such natural demands as farming, hunting, lumbering, and the like, the demand for

vilization react upon the majority of mankind so that artificial substitutes of organized exercise become necessary.

We may regard the craze for athletics and games as a step against the thwarted instinct for physical toil of a woodsman condemned to a city office or other sedentary a protest represented in the younger subject as a craving something violently competitive.

Later life the intrusion of serious interests and responsibilities tends to prohibit such activities. But, although there is great variability in application, an instinctive impulse exists in the majority of cases. What is often overlooked is the social side of exercise, the factor of recreation, the satisfaction of the play instinct. Golf, shooting, fishing, croquet, tennis, bowls, butterfly-hunting, the collection of plants, minerals, and fossils, photography, and similar outdoor games utilize in greater or less degree the exercise of living in an attractive form when walking alone would be instantly accepted as insipid or boring.

With respect to the danger of continuance into middle age the more strenuous exertion of youth, it seems to be a matter of adjustment to exercise, just as the human body can acclimatize to high altitudes, to extremes of temperature, or almost anything. And although it is unusual for the middle-aged man to persist with the exertion of his earlier days there is no reason why such continuance should be exceptional. Youth may thus be prolonged and middle age postponed, at least so far as the tissues are under consideration, not the mere passage of time. But it is the attempt to make exercise after a period of inactivity which is the usual cause of discomfort or catastrophe.

In the case of the man who through inclination, determination, or exceptional opportunity has thus extended the period of youth the danger which is generally advanced of "heart disease" with its implications has no foundation. Nature imposes a salutary restriction by the gradual immobilization of joints, automatically limiting activity to a degree well within the capacity of the cardiovascular system.

Prefrontal Leucotomy

Q.—Where can I find an account of the historical development and present technique of prefrontal leucotomy? How successful is it, and is any special post-operative treatment needed?

A.—An adequate history of the development of prefrontal leucotomy has yet to be written. Furthermore, the technique of every surgeon differs somewhat. Mr. McKissock has provided an account of his operative technique and directions for post-operative care in *J. ment. Sci.*, 1943, 89, 194, and *Lancet*, 1943, 1, 361. A very full discussion of prefrontal leucotomy by a number of experts was reported in *Proc. R. Soc. Med.*, 1946, 39, 443—this is well worth referring to. It contains a critical review on recent literature in *J. ment. Sci.*, 1941, 90, 486. A tome covering all aspects of the subject has been written by the American authorities W. Freeman and J. W. Watts (*Psycho-surgery*, Thomas, Springfield, Ill., 1941). And, finally, there is a recent summary of mental and physical results (*Prefrontal Leucotomy*, H.M. Stationery Office, 1947).

Stellate Ganglion Block for Cerebral Thrombosis

Q.—Stellate ganglion block has been performed in America for the treatment of early cases of cerebral thrombosis. Is the procedure of any value, and what literature exists on the subject?

A.—Stellate ganglion block was first used for the treatment of patients with cerebral thrombosis by Leriche and Fontaine (*Chir., Paris*, 1936, 55, 755). Mackey and Scott (*British Medical Journal*, 1938, 2, 1) reported their experiences with this method. They concluded that some initial improvement did occur provided the procedure was undertaken soon enough after the vascular accident. The degree of improvement depended largely upon the status of the other cerebral arteries. If it had any use they felt that the most favourable of cases would be one of cerebral embolism in a young person. There does not appear to have been much published about the method recently.

Pain in Phantom Foot

Q.—What is the correct treatment for severe pains in a "phantom" foot? This patient's right leg was amputated twenty years ago and the stump is apparently healthy.

A.—The problem of the painful phantom limb is one which has not been satisfactorily solved. Sensations in the lost extremity are of course experienced for a while by almost all those who have undergone amputation. Such sensations are usually painless, and tend to pass off in the course of time. Painful sensations in a phantom limb are relatively uncommon. The cause is unknown—in many cases the stump has healed rapidly and appears satisfactory on examination. Treatment is difficult and often ineffective. Measures which have been tried and which require consideration include excision of stump neuromata; division of the nerve trunks proximal to the end of the stump; and section of the appropriate posterior nerve roots. But the symptoms commonly persist in spite of these procedures. Re-amputation at a higher level is also unlikely to be successful. The management of these cases is thus distressingly difficult. It is beneficial for the patient to wear his prosthesis if it can be tolerated, and this should be encouraged.

Thiouracil in Toxic Goitre

Q.—I have read the article entitled "Thiouracil in Toxic Goitre" in the *Journal* of Nov. 15, 1947 (p. 759), and have a question to put as regards continuation of thiouracil for longer periods. Is it possible that after recovery from initial hyperthyroid symptoms the dosage of thiouracil can be gradually reduced and finally replaced with Lugol's iodine or potassium iodide for maintenance therapy? Can iodine alone, or with thiouracil, be used for prolonged maintenance therapy?

A.—It is true that after initial control of symptoms the dose of thiouracil can be reduced to 100 mg. daily or less and the patient thus maintained in good health. In a certain proportion of cases the drug can be discontinued after six months or more and symptoms do not recur. This is true of the diffuse toxic goitre of young persons, which is often a self-limiting disease; but in the middle-aged patient with a nodular goitre relapse almost always follows within four months of withholding thiouracil. The beneficial effects of iodine are of much shorter duration, and it is usual to find that there is maximal improvement 14 to 21 days after beginning treatment. It is unusual for this improvement to be maintained, and there are no *a priori* reasons for thinking that it would be effective in the manner suggested, although no record of its use in this fashion has been found.

Heart Attack After Alcoholic Excess

Q.—A patient aged 30, waking up after a bibulous night, presented an irregularly irregular pulse which persisted for twenty-four hours. The heart appears normal. There is a history of rheumatic fever, without cardiac involvement, at the age of 20. What is the prognosis, and is this kind of attack unusual? Could it occur in a normal heart?

A.—This attack was presumably due to the toxic action of alcohol on the heart, which is occasionally seen in susceptible persons. The prognosis is excellent provided that the subject avoids alcoholic excess. The signs observed can occur in a normal heart.

Incontinence of Urine in the Elderly

Q.—A patient aged 80 is suffering from incontinence of urine. Her general health is fairly good, except for slight anginal attacks. She passes large quantities of urine which contains no sugar. Is any operation of use, or is there any appliance she could wear?

A.—It is not stated whether the incontinence is due to a fistula or to a defect in the urethral sphincter mechanism. In either case there appear to be several contraindications to surgical treatment. If it can be assumed that the case is one of urethral incontinence, then it may well be due to senile atrophy of muscles and fascia in the region of the bladder-neck and urethra. A vaginal pessary is not likely to help unless the patient has a cystocele as well. Urinary infection,

nerve lesions, and other possible aetiological factors should be excluded. If all these are excluded, oestrogen in small doses should be tried; a suitable trial dose would be oestrone, 0.3 mg. thrice daily by mouth for three weeks, followed by an interval of seven to ten days, and then repeated. If too much is given it will cause uterine bleeding. A surgical appliance that might be tried is a female urinal strapped to the vulva; but apparatus of this type is rarely satisfactory. Replies to questions published in the *Journal* of Jan. 27, 1945 (p. 139), and Dec. 1, 1945 (p. 792), should also be consulted.

Cellulitis of the Nose

Q.—A patient suffers from a recurring cellulitis of the nose. It seems to arise from an infection caused by an irritation or by microscopic cracks at the margins of the nostrils. I have treated it with various ointments, including penicillin, and find that the daily application of *mg. hydr. ox. flav. dil.* is the best way to control it. The patient, 68 years old, is healthy, and has given up tobacco because the smoke made the nose worse. Can you suggest an effective cure?

A.—If the vestibular fissuring is not due to intranasal infection (ethmoiditis, etc.) or some other local focus of infection, penicillin parenterally and sulphonamide therapy by mouth should be tried after investigating the sensitivity of the organisms concerned. Small fractional doses of x rays are sometimes effective, and sulphathiazole snuff might be tried.

Döderlein's Bacillus

Q.—(a) What is Döderlein's bacillus? (b) Is it a harmless saprophyte found only in the vagina? (c) Does the fact of finding this bacillus in a vaginal smear indicate that any treatment is necessary? (d) Is it at all harmful to the male (following coitus)?

A.—(a) A species of *Lactobacillus* leading a purely saprophytic existence in the vagina of the adult woman, where the acid reaction due to the formation of lactic acid from glycogen in the vaginal epithelium favours its growth. (b) Yes. (c) No. (d) No.

Flatus in the Elderly

Q.—What is the pathology of the flatulence, and particularly flatus, which afflicts many elderly people nowadays? Is there an effective treatment?

A.—There are no essential differences between the flatulence of the elderly and that of younger persons. In both instances gastric flatulence is almost always due to swallowed air, and intestinal flatulence to gas generated locally. The latter is due either to excessive carbohydrate fermentation or to excessive protein putrefaction. The diet provided by the present rations, although sufficient safeguard from the latter, is on account of its high carbohydrate content the cause of the prevailing intestinal wind. In the elderly the affliction is more troublesome perhaps because of decreased intestinal tone. Treatment consists in reducing, so far as is possible, the consumption of bread and potatoes. Charcoal and kaolin may do much to decrease discomfort.

Spondylitis Ossificans

Q.—During a bombing raid in 1940 a policeman was trapped under falling masonry and sustained a fractured skull. He recovered from the injury, but a year later developed spondylitis ossificans, which has progressed so that his head is held at an angle of about 60 degrees to his spine. A board held that the spondylitis could not have been caused by the trauma sustained a year previously. Is this view probably correct?

A.—If this is in fact a true case of ankylosing spondylitis, as it appears to be from the description given, it is probably correct to state that the spondylitis is not related to the trauma previously sustained. Although the cause of ankylosing spondylitis is not known with any certainty, it is accepted fairly widely that it results from a low-grade infective process—a view which is supported by the usual course of the disease and by the raised blood sedimentation rate during the stage of activity. Trauma has not been shown to be a significant factor in the aetiology; indeed, in most cases of ankylosing spondylitis no definite history of major trauma is obtained.

Treatment of Amoebiasis

Q.—Would you let me have information on any recent advances in the treatment of amoebiasis?

A.—There has been little recent advance in the specific treatment of amoebiasis. Combined treatment with emetine bismuth iodide, chiniofon, and acetarsol or carbarsone remains the standard therapy usually employed in British practice for intestinal amoebiasis, while emetine hydrochloride is the specific agent used when the liver or other organs are infected. For intestinal infections "diiodoquin" is advocated; it is less easily absorbed than chiniofon, but its therapeutic superiority is doubtful. If there is much ulceration of the gut, with secondary infection, a course of penicillin and some sulphonamide compound is now commonly used in association with the specific amoebicidal treatment.

NOTES AND COMMENTS

Great Anticipations.—Mr. E. WATSON-WILLIAMS (Clifton, B.) writes: "If the nerve is successfully located . . . relief for eighteen months is to be anticipated" (April 10, p. 718). This has no meaning: the relief may be desired, or expected—it can possibly be anticipated. Even Fry's famous advertisement distinguishes "expectation" from "anticipation."

Apology.—Messrs. Menley and James, Ltd., manufacturers of Coldharbour Lane, London, S.E.5, write: Our attention has been drawn to the leaflet published by us entitled "A Symposium on the uses of 'Benzedrine.'" This contained abstracts of extracts from papers read at a meeting of the Society for the Study of Addiction, by Dr. Crichton Miller, Professor R. C. Brown, Dr. G. de M. Rudolf, amongst others, dealing with the effects of amphetamine. It is represented to us that this pamphlet was worded as to give the impression that these gentlemen were advocating the use of "benzedrine" tablets, a proprietary preparation of amphetamine sulphate manufactured and distributed by us. We regret very much if the pamphlet was so worded as to give the impression and desire to make it clear that the gentlemen in question were not consulted and had no part in the preparation and publication of this pamphlet.

INCOME TAX

Expenses

L. D. is acting as a locumtenent but will shortly be taking up appointment as house physician. He inquires as to certain travelling and other expenses.

* (a) Use of car while at the hospital for travelling to the pathological centre. A reasonable proportion of the actual expenses is allowable provided that visiting the centre is part of the work required under the service agreement with the hospital authority.

(b) Purchase of medical books and instruments. The cost of getting together a medical library is not allowable—it represents an outlay of capital. The cost of keeping it up to date is allowable provided that the maintenance of a private reference library is required under the contract of employment.

(c) L. D. should ask for the locumtenent fees to be assessed under Schedule D. In that case he can claim the cost of one journey to and from the place where the work is done and also other expenses such as any commission paid by him. But the cost of a visit home is, we fear, likely to be refused as not incurred in the work for which the fees are received.

(d) Generally the rule under Schedule E (relating to employment) is a very rigid one; to be allowable the expenses must be wholly, exclusively, and necessarily in the performance of the duties of the employment.

All communications with regard to editorial business should be addressed to the EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. Telegrams: Westcent, London. ORIGINAL ARTICLES AND LETTERS for consideration for publication are understood to be offered to the British Medical Association unless the contrary be stated.

Authors desiring REPRINTS should communicate with the PUBLISHER, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1, on receipt of proof. Overseas should indicate on MSS. if reprints are required, as they are sent abroad.

ADVERTISEMENTS should be addressed to the ADVERTISING MANAGER, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. (Hours 9 a.m. to 5 p.m.) TELEPHONE: EUSTON 2111. TELEGRAMS: BRIMMEDIST, WESTCENT, LONDON.

MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY, BRITISH MEDICAL ASSOCIATION, TELEPHONE: EUSTON 2111. TELEGRAMS: MEDASSOC, LONDON.

B.M.A. SCOTTISH OFFICE: 7, Drumshugh Gardens, Edinburgh.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY APRIL 24 1948

STATEMENT BY COUNCIL

Following statement has been sent by the Council of the Medical Association to every member of the profession.

General

February plebiscite demonstrated that the profession by an overwhelming majority was opposed to the National Health Service Acts and to acceptance of service under them.

The March the Representative Body of the Association passed the following resolution:

At the Representative Body, reaffirming the whole-hearted devotion of the medical profession for a comprehensive health service available to everyone, urges that in the public interest such changes be made in the National Health Service Acts of 1946 and in the Acts as are necessary to maintain the integrity of Medicine and to prevent doctors being turned into State servants, with harmful consequences to patient and doctor alike. The Representative Body hereby expresses the hope that the Government will make it possible for the profession to co-operate by making such changes, and states its view that it is not in the best interests of the public to have Medicine for members of the profession to enter the Service unless such changes are made."

The Chairman of Council summarized the profession's position, in his speech to the Representative Body, he said: "We are ready to enter into any discussions directed to making possible for the medical profession to co-operate with the Government. If the Government can show us other ways, new ways, of saving our independence we are willing to listen."

Obviously these events had their effect on public and political opinion. Eventually the Minister, on behalf of the Government, made a statement in the House of Commons on April 7 following a meeting with representatives of the Association. Subsequently answered a series of questions put to him by the Association. It falls to the profession carefully and calmly to examine these statements in their relation to the problems on which the profession has taken its stand. We now have the new proposals. In order that the profession, in the most democratic way, determine its views and intentions on the new situation created by these statements, the Council submits the issue afresh to the profession in plebiscite form. It may be that members of the profession regard the issue as substantially unaltered; it may be that they regard proffered concessions as sufficient. In either case it is for individual members of the profession to determine their attitude on the facts before them just as they determined their attitude on the facts before them in February. Whatever action taken, those who act for the profession must have the support of the majority in a vote taken in the light of all known facts.

The first duty is to study the facts. What are the changes to what extent, if any, do they preserve the essential freedom of the profession? The more important changes are briefly summarized below, although in all cases the fuller facts should be studied. One or two points are added, though they are not covered by the Minister's answers.

Amending Legislation

It is now promised.

Whole-time Salaried Service

The profession is opposed to a whole-time salaried service. It believes that the Acts in their present form will lead sooner rather than later to a whole-time salaried service, recognizing that such a service can be introduced by regulations made under those Acts. The Government has undertaken to include in the proposed amending Bill—to be introduced when the report of the Committee now studying partnership problems is available—a provision to make it impossible for a whole-time salaried service to be introduced by regulation.

Hospital and Specialist Services

The replies of the Minister clarify the Government's interpretation and intentions on a number of points. The continuance of part-time specialists at hospitals is promised. Existing staffs of hospitals will be taken over by Regional Hospital Boards and Boards of Governors of Teaching Hospitals. In any reorganization which follows, the Boards "will offer new appointments to their staffs either in their existing or other hospitals, which they will be free to accept or refuse as they will."

The system of medical committees in hospitals is accepted. The Ministry has undertaken that Regional Hospital Boards will be advised that in the appointment of medical members of hospital management committees, the medical staff or staffs of the hospital or hospitals concerned should be invited to submit the names of suitable members of medical staffs.

Private Accommodation

Private pay-bed accommodation is promised; it will lie where it is at present, but the Minister does not commit himself to its future distribution. The Minister does not give an assurance not to take over by compulsory purchase after the appointed day any existing or new private hospital venture, but points out that already he has excluded 200 hospitals.

Freedom of Speech and Publication

The assurance of freedom of speech and publication on matters clinical, professional, and administrative is given and will be embodied in the terms of service of hospital staffs.

Regulations

The Minister does not accept the suggestion of special procedure but describes the existing procedure for ensuring that regulations do not go beyond the Acts. The Ministry has undertaken that regulations affecting medical practitioners will be the subject of consultation with the profession before they are made.

General Practice

Basic Salary

The universal basic salary is abandoned. In his statement to Parliament the Minister limited basic salary to the first three years as a principal with option to all principals. Where basic salary is paid, capitation remuneration would be reduced by one-seventh. In his reply the Minister has agreed to discuss with the profession the conditions and methods of opting, so as to meet the Association's points that basic salary should be paid only where there is need and, except in such circumstances, should not provide a means of opting for higher average remuneration per patient.

Distribution

The Minister does not agree to abandon or to suspend the distribution machinery. In practice it will be limited to those few areas specifically named by the Medical Practices Committee as sufficiently doctored. In other areas consent will be automatic. The Minister offers a special review of the usefulness of the procedure in, say, two years' time.

Goodwill

The Minister insists on the abolition of buying and selling, with compensation, adding that in all areas practitioners will be free to choose their own partners or assistants provided that, in the areas named as sufficiently doctored, permission is obtained for the entrance of new practitioners.

Appeal

The procedure remains as laid down in the Acts without an appeal to the Courts.

Other Points

The Minister has agreed to include certain other matters of detail in the amending Bill including provision for the right of Executive Councils after the initial appointment to elect their own Chairmen.

We have succeeded on some points, such as the bar on the introduction of a whole-time salaried service by regulation, and the universal basic salary. We have failed on others, such as the ownership of goodwill and the right of appeal. The task of the profession is to judge the position in the light of our gains and losses, and in relation to the essential freedoms of the profession. Bearing in mind that what we have secured falls short of what we sought, the Council's view is that while progress has been made to that end, the freedoms of the profession are not sufficiently safeguarded. Whatever your views, please vote in order that the plebiscite may faithfully represent the views of the profession and guide those whose heavy responsibility it is to act on its behalf. Meetings of the profession will be held in your area between April 21 and April 26. Please do your best to attend your local meeting.

Any general practitioner who receives an invitation from a Local Executive Council to say whether or not he will enter the Service is advised not to answer until the profession's view has been determined.

B.M.A. HOUSE, LONDON, W.C.1.

April, 1948.

THE PLEBISCITE FORM

On April 19 the British Medical Association sent out a plebiscite form to all medical practitioners. The object of the plebiscite is to ascertain the views of the profession as a whole on the question of service or no service in the light of the Minister's statement to Parliament on April 7 and his written reply to the questions addressed to him by the B.M.A. (*Journal*, April 17, p. 742). The plebiscite form is in three sections, each section expressing a choice one way or the other. The practitioner marks his choice with an X. Every member of the profession is asked to answer Section A. Consultants and specialists, general practitioners (principals and assistants), and whole-time voluntary hospital staffs are asked to answer all three sections. The questions are as follows:

- | | | |
|---|---|--|
| A | { | I approve of the National Health Service Act, 1946, in view of the modifications now proposed by the Government. |
| | | I disapprove of the National Health Service Act, 1946, notwithstanding the modifications now proposed by the Government. |
| B | { | I am in favour of accepting service under the National Health Service Act, 1946, in view of the modifications now proposed by the Government. |
| | | I am not in favour of accepting service under the National Health Service Act, 1946, notwithstanding the modifications now proposed by the Government. |
| C | { | I agree to abide by the decision of the majority and undertake not to enter the Service if the answers to Section B reveal a majority against undertaking service as defined in paragraph 4 above [of the plebiscite form] and if so advised by the British Medical Association. |
| | | I do not agree to abide by the decision of the majority if it is against accepting service as defined above in paragraph 4 [see paragraph below]. |

If in the aggregate vote under Section B the replies (consultants and specialists, general practitioners, and whole-time voluntary hospital staffs) show a majority against accepting service under the Acts and this majority includes approximately 12,000 general practitioners (out of a present total general-practitioner strength of 20,500), the Association will continue to advise the profession not to enter the Service.

How individuals vote will not be divulged.

HEARD AT HEADQUARTERS**The Doctor Shortage**

The nursing shortage is due to actual shortage of recruits, but the doctor shortage, which will become glaringly manifest and when the National Health Service gets going, is likely to be due, not to a shortage of recruits, but to the lack of means for training them. Up to now there has been no lack of eagerness on the part of young men and women to enter the medical profession. About two years ago the British Institute of Public Opinion recorded that 7.5% of parents would like their son to 'become doctors.' Under the existing educational facilities lack of means need not hinder a promising student; the trouble is the shortage of places available in the medical schools. The Medical Curriculum Committee of the B.M.A., whose report is shortly to be published, found that in many medical schools there were at least ten applicants for each vacancy. Part of this surplus is the post-war "bulge," and many applicants apply for admission to more than one school; the existing medical schools will need to be enabled to increase the annual intake or new medical schools will have to be created.

Protection of Practice

In a copy of the *Athenaeum* dated April, 1838, I found a full-column review of a German work entitled *The Moral Aspects of Medical Life*, by (an earlier) Karl Marx. The book is in the form of letters written to famous medical men of an earlier time, some of them British, praising their character and disapproving. One of them is a letter to Richard Mead, who attended Queen Anne and the early Georges, praising his action on behalf of a professional rival "who would have lain long in the Tower to which his too bold speeches against the Government had consigned him had you not approached the Minister Walpole to set him at liberty. Not satisfied with this, I handed over to him £5,000 received by you as fees for him in the interval of his imprisonment." The professional rival was John Freind, who was made F.R.C.P. on the same day as Mead. Freind, a Tory, offended Walpole and was put in prison. Mead, who was a Whig, looked after his practice and paid him 5,000 guineas (not pounds, according to the English account) on his release. The German writer says, "You gave up to him a sum for fees which in any other country would scarcely have accumulated during a long life, even when helped with governmental salaries." The story is that Mead, being called in to prescribe for the Prime Minister, refused to do so unless released Freind.

Government Training Scheme Ending

Local authorities are finding it increasingly difficult to fill vacancies in posts formerly held by medical officers under the Government scheme for postgraduate training after demobilisation. The Middlesex County Council in at least two of its hospitals has been faced with this situation. At the Middlesex County Hospital, owing to the intimation that its medical officers will not be available in the near future, it has decided to add to the staff as and when the appointments ended seven registrars and nine resident junior house officers, and at the Central Middlesex County Hospital, where some of these training appointments are due to end in the near future, five additional unestablished appointments are now to be filled.

Occupational Health in Russia

The U.S.S.R. is not usually credited with being "coming" with information, and so it ought to be particularly interesting that, since in November last the Industrial Medicine Committee of the Association (now the Occupational Health Committee) agreed to inquire of foreign embassies about occupational health in their respective countries, three have replied, and one of the three is the U.S.S.R., the others being Denmark and Switzerland.

ONE HUNDRED AND SIXTEENTH ANNUAL MEETING, CAMBRIDGE, JUNE 25 TO JULY 2, 1948

President-Elect: SIR LIONEL WHITBY, C.V.O., M.C., M.A., M.D., F.R.C.P., Regius Professor of Physic, University of Cambridge; Master of Downing College, Cambridge

SCIENTIFIC SECTIONS

led programmes of the Scientific Sections will appear in the later issue of the *Journal*, but the meetings of the sections will take place on the following days:

Medicine.—Wednesday, June 30; Thursday, July 1; and Friday, July 2.

Surgery.—Wednesday, June 30; Thursday, July 1; and Friday, July 2.

Gynaecology and Obstetrics.—Wednesday, June 30; Thursday, July 1; and Friday, July 2.

Dermatology and Venereology.—Wednesday, June 30; and Thursday, July 1.

Public Health.—Thursday, July 1; and Friday, July 2.

Diseases of the Chest.—Wednesday, June 30; and Thursday, July 1.

Occupational Health.—Thursday, July 1; and Friday, July 2.

Ophthalmology.—Thursday, July 1; and Friday, July 2.

Otorhinolaryngology.—Wednesday, June 30; and Thursday, July 1.

Physiology and Bacteriology.—Wednesday, June 30; and Thursday, July 1.

Physiology, including Biochemistry.—Wednesday, June 30; and Thursday, July 1.

Preventive Medicine.—Wednesday, June 30; and Thursday, July 1.

Physiology.—Thursday, July 1; and Friday, July 2.

Anatomy and Anthropology.—Friday, July 2.

Immunology.—Wednesday, June 30.

Neurology and Psychiatry.—Friday, July 2.

Microbiology.—Friday, July 2.

Rhino-Laryngology.—Wednesday, June 30.

Ophthalmology.—Friday, July 2.

PROVISIONAL TIME-TABLE

Friday, June 25

9.00 a.m.—A.R.M. Inquiry Office open—Large Examination Hall, Bene't Street.

10.00 a.m.—Annual Representative Meeting—Large Examination Hall, Bene't Street.

11.00 a.m.—Ladies' Club open for Registration—English Speaking Union, Trinity Street.

12.00 p.m.—L. Tours of the Colleges.

1.00 p.m.—Lunch to Overseas B.M.A. Representatives—Pitt Club.

2.00 p.m.—L. Tours of the Colleges.

3.00 p.m.—Representatives' Dinner, Dorothy Café.

Saturday, June 26

9.00 a.m.—A.R.M. Inquiry Office open—Large Examination Hall, Bene't Street.

10.00 a.m.—Annual Representative Meeting—Large Examination Hall, Bene't Street.

11.00 a.m.—Ladies' Club open—English Speaking Union, Trinity Street.

12.00 p.m.—L. Tours of the Colleges.

1.00 p.m.—Photograph of Representative Body.

2.00 p.m.—L. Tours of the Colleges.

Sunday, June 27

9.00 a.m.—Excursion to Hinchinbrook (probably limited to 200).

10.00 a.m.—Concert in Arts Theatre: Piano Recital by Pouishneff.

Monday, June 28

9.00 a.m.—Council Meeting—Small Examination Hall, Bene't Street.

10.00 a.m.—A.R.M. Inquiry Office open—Large Examination Hall, Bene't Street.

9.30 a.m.—Ladies' Club open—English Speaking Union, Trinity Street.

10.00 a.m.—Annual Representative Meeting, Large Examination Hall, Bene't Street.

10.30 a.m.—L. Tours of the Colleges.

2.00 p.m.—Reception Room open for Registration—Platform of Large Hall, Guildhall.

2.00 p.m.—L. Visit to Ely Cathedral (limited to 50).

2.30 p.m.—L. Tours of the Colleges.

8.00 p.m. onwards.—Fellows' Gardens of King's, Christ's, and Pembroke Colleges open.

Tuesday, June 29

9.00 a.m.—Official Opening of Exhibition by President-Elect—Large Hall, Guildhall.

9.00 a.m.—Reception Room open for Registration—Guildhall.

9.30 a.m.—Annual Representative Meeting—Large Examination Hall, Bene't Street.

9.30 a.m.—Ladies' Club open—English Speaking Union, Trinity Street.

10.30 a.m.—L. Tours of the Colleges.

11.00 a.m.—Pathological Museum open—Department of Pathology.

12.30 p.m.—Annual General Meeting—Large Examination Hall, Bene't Street.

3.00 p.m.—Official Religious Service—Great St. Mary's Church.*

4.30 p.m.—Vice-Chancellor's Reception—Christ's College* (limited to 500).

8.00 p.m. onwards.—Fellows' Gardens of Christ's and Pembroke Colleges open.

8.30 p.m.—Adjourned Annual General Meeting and President's Address—Senate House (limited to 1,000).

9.30 p.m.—President's Reception, Old Schools* (limited to 700).

Wednesday, June 30

9.00 a.m.—Council Meeting—Small Examination Hall, Bene't Street.

9.00 a.m.—Reception Room open for Registration—Guildhall.

9.00 a.m.—Exhibition open—Large Hall, Guildhall.

9.30 a.m.—Pathological Museum open—Department of Pathology.

9.30 a.m.—Ladies' Club open—English Speaking Union, Trinity Street.

9.30 a.m.—Notts Ladies' Challenge Cup Competition—Gog-Magog Golf Club.

10.00 a.m.—Leinster and Childe Cup Competitions—Gog-Magog Golf Club.

10.00 a.m.—Scientific Sections.

10.30 a.m.—L. Tours of the Colleges.

2.00 p.m.—Visit to Ely Cathedral (limited to 100).

2.30 p.m.—Tours of the Colleges.

2.30 p.m.—Visit to Papworth.

2.30 p.m.—Scientific Sections.

3.00 p.m.—Garden Party at Trinity College (limited to 200).

4.30 p.m.—Overseas Conference—Small Examination Hall, Bene't Street.

6.00 p.m.—Cocktail Party, Medical Women's Federation (limited to 100 members of the M.W.F.) (at home of Mrs. Mitchell, Thorndyke, Huntingdon Road, Cambridge).

8.00 p.m. onwards.—Fellows' Gardens of Christ's and Pembroke Colleges open.

8.30 p.m.—Civic Reception at the Old Schools* (limited to 500).

Thursday, July 1

9.00 a.m.—Reception Room open—Large Hall, Guildhall.

9.00 a.m.—Exhibition open—Large Hall, Guildhall.

9.30 a.m.—Pathological Museum open—Department of Pathology.

9.30 a.m.—Ladies' Club open.

10.00 a.m.—Scientific Sections.

2.30 p.m.—Visit to Papworth.

2.30 p.m.—L. Tours of the Colleges.

2.30 p.m.—Scientific Sections.

3.00 p.m.—Garden Party at Longstone Hall (limited to 200).

5.00 p.m.—Benediction at the Roman Catholic Church, Hills Road.* Address by His Eminence the Cardinal Archbishop.

7.30 p.m.—Annual Dinner—Dorothy Café (limited to 400).

8.00 p.m.—Organ Recital in King's College Chapel.

8.00 p.m. onwards.—Fellows' Gardens in Christ's, Emmanuel, and Pembroke Colleges open.

Friday, July 2

- 8.30 a.m.—Annual Breakfast of the Medical Prayer Union—Pitt Club (limited to 150).
 9.00 a.m.—Reception Room open—Guildhall.
 9.00 a.m.—Exhibition open—Guildhall.
 9.30 a.m.—Ladies' Club open—English Speaking Union, Trinity Street.
 9.30 a.m.—Pathological Museum open—Department of Pathology.
 10.00 a.m.—Scientific Sections.
 10.00 a.m.—Treasurer's Cup Competition—Gog-Magog Golf Club.
 10.30 a.m.—L. Tours of the Colleges.
 2.30 p.m.—Scientific Sections.
 2.30 p.m.—Tours of the Colleges.
 2.30 p.m.—Visit to Papworth.
 8.00 p.m.—Popular Lecture by Sir Henry Dale, O.M., G.B.E.—Large Examination Hall, Bene't Street (limited to 800).
 9.00 p.m.—Annual Dance—Dorothy Café (limited to 600).

*Academic Dress should be worn at these functions.

L.=Functions intended primarily for ladies.

ACCOMMODATION IN CAMBRIDGE

As mentioned in the *Supplement* to the *British Medical Journal* of Feb. 28 (p. 31), the lodging accommodation available in Cambridge next June is very restricted owing to the incidence of a number of functions round about the period of the Meeting.

In order that as much accommodation as possible may be at our disposal, the Cambridge Executive has booked all available space in advance. The Colleges have most generously come to our aid and have offered rooms which, with the lodgings already booked in advance, should accommodate about 2,500 persons.

The following is a brief outline of the position and the steps which should be taken by those wishing to book rooms through the Cambridge Executive.

It should be noted that, except for odd rooms falling vacant, no hotel accommodation is now available, and, except for rooms already booked by the Cambridge Executive, there are few, if any, reasonable lodgings to be had. But members are of course at liberty to make their own arrangements for accommodation.

If visitors wish the Cambridge Executive to book rooms for them, it is very important that the form on p. 109 of this issue should be completed and returned as soon as possible to the Executive Officer, Local B.M.A. Office, Guildhall, Cambridge. When rooms conforming as nearly as possible to requirements have been booked, applicants will receive a note giving particulars of the accommodation booked and the charges. A cheque for the amount indicated should be sent to the B.M.A. Office, Guildhall, Cambridge, on receipt of which the booking will be considered definite. This procedure is necessary, as it was only possible to retain the lodging space by firm booking at the end of last year. Cheques should be made payable to the British Medical Association and crossed.

Official Headquarters will be in Newnham College, which will accommodate 100 men or women—either members of the B.M.A. or their wives or other guests. All rooms are single bedrooms, and little or no bedroom service can be given. Full board will be provided and a lounge set aside for the use of members and their friends.

Other Colleges have offered accommodation as follows:

Caius	100 men
Christ's	80 men
Corpus Christi	50 men
Downing	60 men
Emmanuel	100 men
Girton	150 men or women
King's	50 men, and 20 men or women in Hostel
Jesus	100 men
Madalene	60 men
Newnham	20 women (for own members in addition to 100 stated above)
Pembroke	50 men
Peterhouse	50 men
Queens'	100 men
Trinity College	200 men
Trinity Hall	50 men
St. Catherine's	100 men
St. John's	120 men

Sidney Sussex	80 men
St. John's	200 men
Wesley House	17 men and 6 women
Westminster	35 men or women

Each College wishes preference to be given to its own members, and, in the case of Wesley House, Methodist doctors receive first priority.

The charge for all Colleges, including Newnham, is 4s. per person per day, with full board. All rooms are for men and no women can be accommodated except in Newnham, Girton, King's Hostel, Wesley House, and Westminster. In many cases, therefore, wives may have to be put up in lodgings separate from their husbands.

Rooms in lodgings in town are, in general, available for either men or women, and accommodation for approximately 750 has been reserved. Only bed and breakfast can be provided except in a few isolated cases, but arrangements have been made to reserve space in restaurants and elsewhere for lunches and dinners. The uniform charge for lodgings is 4s. per person per night, including breakfast.

Ration books or emergency cards must be brought, and meals can be provided in lodgings or Colleges without them. If visitors are going to stay in College they must bring their books, but if in lodgings emergency ration cards are necessary. Visitors are strongly advised to obtain emergency cards before leaving home, as Cambridge Food Office is overloaded in June and very great delay might occur in obtaining emergency cards here.

Towels and soap should be brought, as in the majority of cases these cannot be provided.

CAR PARKING ARRANGEMENTS

A private car park has been set aside for the use of B.M.A. members at Coe Fen (Entrance from Fen Causeway) from June 24 to July 3. Attendants will be on duty day and night and admission is free to Members displaying the B.M.A. screen label or badge.

Visiting Members are asked to park their cars as soon as they arrive in Cambridge (after depositing luggage at their lodgings) and not to use them while in Cambridge, on account of congestion of traffic and narrowness of streets.

The police ask that no cars should be brought to the Guildhall, and no parking will be allowed in the vicinity of the Guildhall except in the Market Square if space is available.

Members should therefore proceed to the Guildhall (for registration or other purposes) by taxi, by bus, or on foot.

REGULATIONS REGARDING DRESS

Academic Dress.—No hoods are to be worn during the Cambridge Meeting, as the Chancellor will not be present. Robes are to be worn at the Official Religious Service, Tuesday, June 29; the President's Address, Tuesday, June 29; the President's Reception, Tuesday, June 29; the Vice-President's Reception, Tuesday, June 29; the Mayor's Reception, Wednesday, June 30; the Roman Catholic Service, Thursday, July 1. Robes may be hired from Messrs. Ede and Ravenscroft Ltd., 93, Chancery Lane, W.C.2, and may be sent to the B.M.A. Reception Office, Large Examination Hall, Cambridge, if desired.

Evening Dress.—Evening Dress (Tails or Dinner Jacket) with Decorations should be worn at the following functions: President's Reception, Tuesday, June 29; Mayor's Reception, Wednesday, June 30; Annual Dinner, Thursday, July 1; Representatives' Dinner, Friday, June 25, and the Annual Dinner, July 2.

BADGES

Officers of Scientific Sections should inquire for Badges at the Registration Counter, Guildhall.

TICKETS

Unfortunately, owing to the austerity conditions, the numbers attending the various functions will be limited, and early application for tickets at the Registration Counter, Guildhall, is advised.

H.M. Forces Appointments

War Substantive Captain J. D. H. Bankier has relinquished his commission on account of disability and has been granted the honorary rank of Captain.

INDIAN MEDICAL SERVICE

Colonel P. Savage has retired.
Lieutenant-Colonels Sir S. S. Sokhey and H. M. Strickland to be Colonels.
Lieutenant-Colonels N. D. Puri, G. R. Oberai, V. Mahadevan, R. N. Bhandari, G. A. Khan, and I. S. Nalwa have retired.
Lieutenant-Colonel A. Ba Thaw has relinquished his commission.
Major Hoe Min Sein has relinquished his commission.

EMERGENCY COMMISSION

Major R. M. Vanreenan has relinquished his commission on being appointed to a Short Service Commission, R.A.M.C.
Captain J. G. H. Davidson to be Major.

INDIAN ARMY MEDICAL CORPS

Major M. J. Godfrey has retired.

SPECIAL LIST (EX-INDIAN ARMY)

BRITISH ARMY

Major-General W. E. R. Dimond, C.I.E., C.B.E., has retired.
Lieutenant-Colonels T. J. Davidson and A. Rosenbloom have retired and have been granted the honorary rank of Colonel.
Lieutenant-Colonels G. F. Condon and F. R. W. K. Allen have retired.
Major (War Substantive Lieutenant-Colonel) J. W. Bowden has retired and has been granted the honorary rank of Colonel.
Major (War Substantive Lieutenant-Colonel) J. Revans, M.B.E., has retired, receiving a gratuity and has been granted the honorary rank of Colonel.
Majors J. H. Cater, B. J. Doran, J. Reidy, and D. R. Nicol have retired and have been granted the honorary rank of Lieutenant-Colonel.
Major J. E. O'Donnell has retired.
Captains (War Substantive Majors) H. L. Loughran, J. L. M. Whitbread, and G. T. M. Hayes, O.B.E., M.C., have retired and have been granted the honorary rank of Lieutenant-Colonel.

Association Notices

SIR CHARLES HASTINGS CLINICAL PRIZE

The Sir Charles Hastings Clinical Prize, which consists of a certificate and a money award of 50 guineas, is again open for competition. The following are the regulations governing the award:

1. The prize is established by the Council of the British Medical Association for the promotion of systematic observation, research, and record in general practice; it includes a money award of the value of 50 guineas.
2. Any member of the Association who is engaged in general practice is eligible to compete for the prize.
3. The work submitted must include personal observations and experiences collected by the candidate in general practice, and a high order of excellence will be required. If no essay entered is of sufficient merit no award will be made. It is to be noted that candidates in their entries should confine their attention to their own observations in practice rather than to comments on previously published work on the subject, though reference to current literature should not be omitted when it bears directly on their results, their interpretations, and their conclusions.
4. Essays, or whatever form the candidate desires his work to take, must be sent to the British Medical Association House, Tavistock Square, London, W.C.1, not later than Dec. 31, 1948. The prize will be awarded at the Annual General Meeting of the Association to be held in 1949.
5. No study or essay that has been published in the medical press or elsewhere will be considered eligible for the prize, and a contribution offered in one year cannot be accepted in any subsequent year unless it includes evidence of further work. A prizewinner in any year is not eligible for a second award of the prize.
6. If any question arises in reference to the eligibility of the candidate or the admissibility of his or her essay the decision of the Council on any such point shall be final.
7. Each essay must be typewritten or printed, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address.
8. The writer of the essay to whom the prize is awarded may, on the initiative of the Science Committee, be requested to prepare a paper on the subject for publication in the *British Medical Journal* or for presentation to the appropriate Section of the Annual Meeting of the Association.
9. Inquiries relative to the prize should be addressed to the Secretary.

KATHERINE BISHOP HARMAN PRIZE

The Council of the B.M.A. is prepared to consider an award of the Katherine Bishop Harman Prize of the value of £75 in 1948. The purpose of the prize, which was founded in 1926, is to encourage study and research directed to the diminution and avoidance of the risks to health and life that are apt to arise in pregnancy or child-bearing. It will be awarded for the best essay submitted in open competition, competitors being left free to select the subject they wish to present, provided this falls within the scope of the prize. Any medical practitioner registered in the British Medical Association is eligible to compete.

Should the Council of the Association decide that no essay submitted is of sufficient merit, the prize will not be awarded in 1948 but will be offered again in the year next following this decision and in this event the money value of the prize on the occasion of the question will be such proportion of the accumulated interest as the Council shall determine.

The decision of the Council will be final.

Each essay must be typewritten or printed in the English language, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address. Essays must be forwarded to reach the Secretary, to whom all inquiries should be addressed, at B.M.A. House, Tavistock Square, London, W.C.1, not later than Dec. 31, 1948.

MIDDLEMORE PRIZE

The Middlemore Prize consists of a cheque for £50 and an illuminated certificate, and was founded in 1880 by the late Richard Middlemore, F.R.C.S., of Birmingham, to be awarded for the best essay or work on any subject which the Council of the British Medical Association may from time to time select in any department of ophthalmic medicine or surgery. The Council is prepared to consider the award of the prize in the year 1948 to the author of the best essay on "The Value of Orthoptics in the Treatment of Squint." Essays submitted in competition must reach the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1, on or before Dec. 31, 1948. Each essay must be signed with a motto and accompanied by a sealed envelope marked on the outside with the motto and containing the name and address of the author. In the event of an essay being of sufficient merit the prize will not be awarded in 1949.

PROPOSED WEST DERBYSHIRE DIVISION

Notice is hereby given by the Council to all concerned in the proposal to form a West Derbyshire Division with the following area:

The Urban Districts of Matlock, Wirksworth, Bakewell, Rural District of Bakewell; the Civil Parishes of Ashover, Derby, Lea and Holloway, and Crich.

The proposed new Division will form part of the Derbyshire Branch. Any member affected by this proposal and wishing to object thereto is requested to write to the Secretary of the Association by May 24, 1948, stating the objection and the grounds therefor.

CHARLES HILL
Secretary

GROUP OF VENEREOLOGISTS

A meeting of the recently formed Group of Venereologists will be held at B.M.A. House, Tavistock Square, London, W.C.1, on Friday, May 7, 1948, at 2 p.m.

The Group consists of all those members of the Association who are engaged predominantly in the practice of venereology. The agenda will consist of (a) the election of a President, (b) consideration of the size and constitution of the Group, and (c) a general discussion on the work of the Group.

CHARLES HILL
Secretary

5. Wed. Council, 11 a.m.

Branch and Division Meetings to be Held

BIRMINGHAM: CENTRAL DIVISION.—At 154, Great Charles Street, Birmingham. Tuesday, April 27, 8.15 p.m. Clinical Meeting conducted by Dr. E. Davies Thomas.

LONDON SATURDAY MAY 1 1948

PERNICIOUS ANAEMIA OF PREGNANCY AND THE PUERPERIUM

BY

S. P. DAVIDSON, M.D., F.R.C.P.Ed.&Lond.
Professor of Medicine

R. H. GIRDWOOD, M.B., F.R.C.P.Ed.
Lecturer in Medicine

AND

J. R. CLARK, M.B., Ch.B., M.R.C.P.Ed.
Assistant in Department of Medicine

University of Edinburgh

Pernicious anaemia is an uncommon disease, and pernicious anaemia of pregnancy is much rarer still. In 521 cases of macrocytic anaemia examined by us in the past seven years only 31 were associated with pregnancy and of these only four have been seen since the introduction of folic acid. It is therefore not surprising that no report on the therapeutic value of folic acid in this type of megaloblastic anaemia has appeared in the medical literature, and that records of only four cases have been published in America—three cases by Moore (1946) and one by Moore *et al.* (1945). In all three cases folic acid was given by the parenteral route and a satisfactory response was obtained in two. We now submit records of three cases of pernicious anaemia of pregnancy and one case of pernicious anaemia that relapsed as a complication of pregnancy, all of which responded to folic acid. The haemoglobinometer used in this investigation was a Haldane instrument standardized by the Physical Laboratory.

Case 1

A woman aged 30 was admitted to our wards on 15.12.1947, on account of severe anaemia. Her first pregnancy was in December, 1944, and the second in 1946. Because of anaemia she was treated in hospital before parturition and with anahaemin for three months and gradually made a good recovery. No information was available in regard to the type or the severity of the anaemia. In 1947 she again became pregnant and was confined during hospital on Nov. 2. Twins were delivered, and a considerable amount of blood. No information was available of her blood previous to this confinement was more than the fact that her haemoglobin was 48% one month before delivery. During this month she was given 6 gr. of ferrous sulphate thrice daily and 2 ml. of anahaemin daily. Consequently on the loss of blood at parturition her haemoglobin level fell to 40%.

On admission to our wards questioning revealed that her medical history was satisfactory and that there was no history of anaemia or of diarrhoea. The patient had been abroad and had never suffered from dyspepsia, or diarrhoea. Physical examination revealed no abnormality of the tongue, finger-nails, or skin. There was no objective evidence of involvement of the nervous system. No source of blood loss was discovered. There

was no jaundice or fever. The liver, spleen, and lymph nodes were not enlarged, and no pathological features were found in any system other than the haemopoietic system. A test meal revealed free hydrochloric acid in all specimens, and the urine contained an excess of urobilinogen. Her blood count on Nov. 14 was: red cells, 1,570,000 per c.mm.; haemoglobin, 30%; colour index, 0.96; reticulocytes, 1.4%; white cells, 12,400 per c.mm. A megaloblastic bone marrow indistinguishable from that of Addisonian pernicious anaemia was found. Folic acid was given in a dosage of 20 mg. daily by mouth for 12 days, and thereafter 10 mg. daily. This resulted in a reticulo-

FIG. 1.—Chart of Case 1. ---- indicates counts done before we saw the patient.

cyte peak of 31% on the fifth day and an increase of red cells and haemoglobin of 2,400,000 and 58% respectively in 55 days. (Fig. 1.)

Case 2

This patient, a married woman aged 23, was admitted to the Simpson Memorial Maternity Pavilion of the Royal Infirmary, Edinburgh, on Jan. 29, 1948, with a diagnosis of pre-eclamptic toxemia because of oedema, albuminuria, and hypertension. On Feb. 7 she was delivered of a healthy full-time female child. There was no history of previous pregnancy or of miscarriages. A haemoglobin level of 60% was found the day before the baby was born.

The patient said she had always been pale, but the only serious illness she had had was diphtheria at the age of six, which was followed by a right-sided hemiplegia. There was no family history of anaemia or diarrhoea. She was pale and slightly built, had never suffered from dysphagia, dyspepsia, or diarrhoea, and had never been abroad. Her dietetic history was satisfactory. There was no enlargement of the liver, spleen, or lymph nodes. The tongue was slightly atrophic, with several

sore patches, and the finger-nails showed some ridging. There was no jaundice, and no source of blood loss was discovered. The urine contained albumin and a marked excess of urobilinogen. A test meal showed histamine-fast achlorhydria. The blood pressure was normal, and no disease was found in the cardiovascular or respiratory system. Apart from the residual signs of the hemiplegia mentioned above no abnormality of the nervous system was found.

A blood count carried out by us on Feb. 20 was as follows: red cells, 2,300,000 per c.mm.; haemoglobin, 44%; colour index, 0.9; white cells, 4,000; reticulocytes, 1.2%. The bone marrow was megaloblastic and indistinguishable from that of untreated Addisonian pernicious anaemia, despite the fact that 2 ml. of anahaemin had been given on three consecutive days before sternal biopsy was undertaken. Eight days later the blood count was slightly lower and the M.C.V. was 84 c. μ . The state of the bone marrow could not be ascertained, since the patient refused to have a second sternal puncture. The presence of an occasional megaloblast in the peripheral blood suggested that no change had occurred. Accordingly treatment with folic acid was started, a single injection of 30 mg. being given intramuscularly, followed by 10 mg. by mouth daily. This resulted in a reticulocyte peak of 26% on the fifth day, and an increase of 1,380,000 red cells and 12% haemoglobin in 18 days. At this date the colour index was 0.75, and the hypochromic appearance of the erythrocytes clearly indicated the need for supplementary iron therapy.

Case 3

A married woman aged 30 was transferred to our wards from the Simpson Memorial Maternity Pavilion on Feb. 26, 1947, on account of severe anaemia. She had given birth to a healthy son on Feb. 14 and had had no previous pregnancies. Labour had been uneventful except that there had been a moderately heavy blood loss after delivery of the placenta. There was no family history of anaemia or diarrhoea. Her appetite was good. The patient's dietetic history was satisfactory and she had never suffered from dysphagia, dyspepsia, diarrhoea, anaemia, or any serious illness. Physical examination revealed no abnormality of the heart, lungs, abdominal organs, or nervous system. There was some atrophy of the papillae of the tongue; neither koilonychia nor enlargement of lymphatic nodes was found. The blood pressure was 124/90. The urine contained a trace of albumin but no excess of urobilinogen. There was free hydrochloric acid in the gastric juice.

When we first saw the patient on Feb. 26 the blood count was: red cells, 1,800,000 per c.mm.; haemoglobin, 46%; colour index, 1.28; white cells, 6,800 per c.mm.; reticulocytes, 5.6%. The M.C.V. calculated on two occasions was 107 and 114 c. μ . The marrow was megaloblastic. The patient had been treated with 6 gr. (0.4 g.) of ferrous sulphate three times a day during pregnancy, but had never received liver by mouth or by injection. At the end of a control period of ten days the red cell count was unaltered and the reticulocyte count had fallen to 1.8%. Accordingly, 10 mg. of folic acid daily was given by mouth. She had to leave hospital on account of domestic difficulties, but continued to take the folic acid as an out-patient, reporting at regular intervals to the blood clinic for assessment of progress. A rapid improvement in her general clinical condition resulted, while a gain of 1,410,000 red cells and 10% haemoglobin occurred in 35 days. She was then given 18 gr. (1.2 g.) of ferrous sulphate daily and the blood count was restored to normal.

Case 4

This patient, an unmarried woman aged 38, was in the sixth month of pregnancy when we were asked to see her because of severe anaemia which had failed to respond to treatment with iron and various preparations of liver.

In 1940, at the age of 30, she had been admitted to the Royal Infirmary of Edinburgh suffering from severe anaemia. The following information was obtained from her case records. Before admission she had been getting increasingly pale, easily tired, and breathless, and vomiting and diarrhoea had occurred. There was oedema of the ankles, the skin had a lemon-yellow colour, and the conjunctival mucous membrane was very pale. Apart from atrophic glossitis, anaemia, and achlorhydria, no

abnormality was noted in any system. Her blood count^E April 15, 1940, was: red cells, 1,720,000 per c.mm.; haemoglobin, 45%; colour index, 1.3. Intensive treatment with parenteral liver extract was given. She received an intramuscular injection of 5 ml. of "pernaemon" daily. As the response was poor, "campolon," one ampoule daily, was sub-

FIG. 2.—Bone marrow from Case 4, showing persistence of megaloblastic erythropoiesis despite administration of 32 ml. anahaemin, 6 ml. plexan, and 3½ oz. (115 g.) of hepamino over a period of 3 weeks. (×1,400.)

stituted. The response continued to be poor, and despite this intensive treatment the gain in red cells and haemoglobin over a period of two and a half months was only 1,500,000 red cells and 25% haemoglobin. After discharge from hospital the patient continued to have injections of liver extract from her doctor, at first daily and then weekly for the next two years.

FIG. 3.—Bone marrow from Case 4, showing reversion to normoblastic erythropoiesis 36 hours after the intramuscular administration of 60 mg. of folic acid. (×1,400.)

In 1942 she had two severe reactions following the injection of liver extract. When anahaemin was substituted for the previous liver extract no reactions followed. The doctor states, however, that the patient attended for treatment irregularly and at long intervals during the next five years. Throughout this period she was pale, breathless, and easily tired, but continued working

form of a small tasteless tablet and because of the rapid clinical and haematological improvement which results even in cases refractory to parenteral liver therapy. Since the duration of treatment with folic acid is limited to a few weeks, the danger of producing subacute combined degeneration of the cord is greatly reduced as compared with Addisonian pernicious anaemia. Further time must elapse, however, before it can be stated confidently that neurological features will not occur in patients with pernicious anaemia of pregnancy receiving folic acid.

As many cases of pernicious anaemia of pregnancy are suffering from a dual deficiency of iron and the factor required for maintenance of normoblastic blood formation it is desirable that both deficiencies be corrected simultaneously. While our patients were receiving folic acid iron was deliberately withheld in order to simplify the interpretation of the therapeutic response.

(Anahaemin is a refined liver extract, and "plexan" and "campolon" are crude extracts.)

Summary

Three cases of pernicious anaemia of pregnancy and one case of Addisonian pernicious anaemia complicated by pregnancy responded excellently to treatment with folic acid. Three of the cases had failed to respond to the parenteral injection of liver extracts prior to the administration of folic acid.

We wish to thank Prof. Kellar, Dr. Fahmy, and others of our colleagues in the Simpson Memorial Maternity Pavilion of the Royal Infirmary, Edinburgh, for permission to investigate and treat the above cases.

FOLIC ACID*

BY

JOHN F. WILKINSON, M.D., M.Sc., Ph.D.
F.R.C.P., F.R.I.C.

Hon. Physician; Director of Department of Haematology,
Royal Infirmary and University of Manchester

Idiopathic Steatorrhoea and Coeliac Disease

A number of reports have now appeared on the excellent effect of "folic acid" in the treatment of tropical sprue (Darby and Jones, 1945; Darby *et al.*, 1946a, 1946b; Spies, 1946a, 1946b; Spies *et al.*, 1946; Manson-Bahr and Clarke, 1946; Morrison and Johnston, 1947); while Davidson and Girdwood (1947) and Weir and Comfort (1947) have described their results using it on patients with non-tropical sprue, particularly those with normoblastic marrows.

*The conclusion of the lectures (abridged) given to the Section of Experimental Medicine of the Royal Society of Medicine on May 13, 1947, and to the Medical Society of London on Feb. 9, 1948.

The following four cases illustrate my results with pteroylglutamic acid is used on patients with idiopathic steatorrhoea (non-tropical sprue) and coeliac disease (Table V).

Idiopathic Steatorrhoea

The diagnostic criteria for patients with idiopathic steatorrhoea (non-tropical sprue) were: (1) a macrocytic anaemia with a megaloblastic or normoblastic marrow; (2) frequent loose, bulky, offensive stools, often yellow in colour; (3) high total fat content of stools with or without a prior fat test meal; (4) achlorhydria gastrica or normal acidity; (5) soreness or ulceration of the mouth or tongue; (6) severe loss of weight; and (7) a flat glucose-tolerance curve.

Case I.S.—A housewife aged 53 had an eight-months history of tiredness, lack of energy, palpitation, intermittent soreness of the tongue, increasing pallor, and frequent loose, bulky, offensive, yellowish stools up to eight in 24 hours. She had lost at least 3 st. (19 kg.) in weight. The bone marrow was very cellular and active, with a mixed megaloblastic (5%)–normoblastic (27%) hyperplasia. A blood count showed: R.B.C. 2,610,000; Hb, 72%; C.I., 1.33; W.B.C., 6,600 (polymorphs 73%, lymphocytes 22%, large monocytes 3%, eosinophils 2%); marked anisocytosis and poikilocytosis; reticulocytes, 3.2. Stools: total fat, 55% (split fat 83%, unsplit 17%). She was given 20 mg. of pteroylglutamic acid orally per day. There was a slight reticulocytosis (4.2% on the 8th day) and the haematological response was slow but ultimately (after 64 days) a normal R.B.C. 4,140,000, Hb 82%, C.I. 1, W.B.C. 7,100, with a normal differential white cell count. The stools rapidly improved, became formed, and ceased to be frequent, bulky, or offensive; total fat, 28% (split 84%, unsplit 16%). Clinically the patient had improved very much indeed; she was free from symptoms and was gaining weight steadily when discharged from hospital.

Case B.C.—A housewife aged 35 had had tetany intermittently since the age of 24; she had bilateral cataracts and frequent bulky offensive stools in addition to the usual general symptoms. Examination revealed achylia gastrica, a flat glucose-tolerance curve, a negative Wassermann reaction, a normal C.S.F.; serum calcium varied between 6.4 and 9.8 mg. per 100 ml., blood urea 22 mg. per 100 ml., urea clearance 85%, serum phosphorus 3.6%, plasma alkaline phosphatase 4 units; radiologically there was some generalized osteoporosis of the long bones; weight, 4 st. 12 lb. (30.84 kg.); blood pressure, 100/70. A blood count on June 27, 1946, showed: R.B.C., 3,210,000; Hb, 74%; C.I., 1.16; W.B.C., 3,600 (polymorphs 59%, lymphocytes 36%, large monocytes 4%, eosinophils 1%); anisocytosis and poikilocytosis marked; platelets, 97,000. The marrow was very active and cellular and showed a mixed megaloblastic (4.7%)–normoblastic (9.7%) hyperplasia. Stools: total fat, 41% (split fat 82%, unsplit 18%). Bacteriological examination of faeces did not disclose any abnormality.

The patient had 15 mg. of pteroylglutamic acid intramuscularly daily for 10 days without any clinical or haematological response, and was then given 1 oz. (28 g.) orally of proteolysed liver extract daily without improvement, the blood count on Aug. 9 being rather worse: R.B.C., 2,820,000; Hb, 62%; C.I., 1.11; W.B.C., 7,200. At this stage the marrow showed a normoblastic (49.25%) hyperplasia. Continued treatment with liver extract parenterally, supplemented with synthetic vitamins of the B complex, hog's stomach, etc.

TABLE VI.—*Aplastic Anaemia*

Case	Sex	Age	Marrow	R.B.C. $\times 10^6$	Hb %	W.B.C.	Platelets	Folic Acid Dosage
J.S.	M	44	Aplastic	1.52 1.60 (7)	30 30 (7)	4,200 2,700 (7)	40,000 25,000 (9)	150 mg. i.v.
P.S.	M	6	"	1.37 0.85 (56)	18 20 (56)	1,800 1,400 (56)	35,000 246,000 (56)	5-100 mg. orally dai.
M.L.	F	53	"	1.08 (308) 1.38	24 (308) 26	1,800 (308) 3,800	30,000	100 mg. i.v. 20 mg. orally daily

was given to three patients with typical aplastic anaemia (see Table VI): all had aplastic marrows and all failed to show the slightest clinical or haematological responses after doses varying up to 150 mg. a day intravenously and orally. Similar negative results were noted in patients with agranulocytosis and the cases of chronic neutropenia given up to 150 mg. daily, intravenously or orally, in contradistinction to the changes noted in rats (see above), while thrombocytopenia purpura (two cases secondary to gold therapy) also resisted this treatment.

Of course, as shown above, where there is haematological response to treatment, as in pernicious anaemia and similar megalocytic anaemias, all the cellular elements of the blood benefit, so that with the red cells there is concomitant improvement in the numbers of white cells and platelets, as occurs after liver and stomach therapy.

Leukaemias

A large number of cases of acute and chronic leukaemia were given synthetic pteroylglutamic acid without benefit. Thus patients with acute myeloblastic, lymphoblastic, and monocytic leukaemias who received up to 150 mg. intravenously and 20-80 mg. orally daily did not show improvement in their haematological or in their general clinical conditions. In chronic myeloid and lymphatic leukaemias no better results were seen, but two of my old patients with pernicious anaemia who developed chronic myeloid leukaemia showed marked general improvement in the pernicious anaemia but subsequently failed to maintain it.

Patient E.O., a woman aged 40, was first seen by me in 1932, when pernicious anaemia was diagnosed: her case has been reported by my chief assistant, Dr. Woolley (1944). She remained well until 1942 when, after five years' absence, she was found to have a large spleen—6 in. (15 cm.) below the costal margin—due to a chronic myeloid leukaemia, with R.B.C., 2,680,000; Hb., 48%; C.I., 0.92; W.B.C., 85,600 (polymorphs 59.8%, lymphocytes 7.2%, large monocytes 0.4%, eosinophils 2.4%, basophils 6.6%, metamyelocytes 14%, myelocytes 9%, myeloblasts 0.6%); normoblasts 6 in 500, megakaryoblasts 8 in 500 white cells. The sternal marrow puncture showed a chronic myeloid leukaemia picture with also normoblasts 6.6% and megakaryoblasts 6.6%. She did quite well on anti-pernicious-anaemia treatment with liver extract and additional x-ray therapy, and later urethane (1-3 g. daily), but on Feb. 13, 1947, the blood count had become worse, with R.B.C., 3,720,000; Hb. 74%; C.I., 1; W.B.C., 120,500. No improvement was shown haematologically on 20-40 mg. of pteroylglutamic acid daily.

Patient G.G., a woman aged 52, was originally seen in 1940 with pernicious anaemia which responded normally to routine treatment for four years, but on Oct. 16, 1945, she returned to my clinic with a spleen 2 in. (5 cm.) below the costal margin and a blood count of R.B.C., 3,610,000; Hb. 82%; C.I., 1.12; W.B.C., 82,600 (polymorphs 54.5%, lymphocytes 9.5%, large monocytes 4.5%, eosinophils 1.5%, basophils 4.5%, myelocytes 15.5%, metamyelocytes 3.5%, myeloblasts 6.5%); nucleated red cells, 4 in 200 white cells. Marrow biopsy showed a typical chronic myeloid leukaemia with no megakaryoblasts to be seen. The patient responded very well to liver extract and urethane, but after severe haematuria she had (Feb. 15, 1947) R.B.C., 1,710,000; Hb. 34%; C.I., 1; W.B.C., 219,500; and a typical myeloid leukaemia marrow with very few megakaryoblasts and

normoblasts. She was given pteroylglutamic acid, 30 mg. orally, with improvement to April 9 (R.B.C., 3,260,000; 64%; C.I., 0.98), without any further increase subsequently. The white cell count fell to 7,900 (polymorphs 53%, lymphocytes 5.5%, monocytes 2%, eosinophils 1.5%, basophils 3%, myelocytes 24%, metamyelocytes 10%, myeloblasts 1%) following a course of tri- β -chloroethylamine hydrochloride.

Two patients with leuco-erythroblastic anaemia did show any clinical or haematological response to synthetic pteroylglutamic acid in daily doses of 20-30 mg. orally in periods up to 38 days.

Miscellaneous Blood Diseases

Synthetic pteroylglutamic acid has also failed to show any clinical or haematological improvement in many other blood conditions not having megaloblastic marrow hyperplasia, such as acute and chronic haemolytic anaemia, microcytic hypochromic anaemias, anaemias secondary to hyperthyroidism and myxoedema, toxic anaemias, etc.

Recently Farber *et al.* (1947) reported their preliminary and somewhat favourable results in the treatment of 17 cases of malignant disease with two synthetic pteroylglutamates—pteroyldiglutamic acid ("diophterin") and pteroyltriglutamic acid ("terophterin"). Apparently pteroylglutamic acid was without effect, and these observers say that there is no evidence to indicate that those substances should be used in routine therapy.

Discussion

Evidence has been accumulating as to the value of this new synthetic anti-macrocytic-anaemia constituent of the vitamin B complex. It is quite clear that in general those anaemias with megaloblastic marrows respond to pteroylglutamic acid, however administered, while those with normoblastic, aplastic, or hypoplastic marrows do not.

Thus of the megaloblastic anaemias that respond we have pernicious anaemia, possibly achrestic anaemia, and macrocytic anaemias of pellagra, sprue, idiopathic steatorrhea, pregnancy, infancy, and nutritional deficiencies. In the sprue syndrome, coeliac disease and steatorrhea the response varies in response according to the type of marrow activity; with a megaloblastic marrow the response may be good for a time, but these patients tend to relapse with the return of the loose, bulky, fatty stool. Less satisfactory results are obtained when the marrow is normoblastic, although these patients do not respond haematologically, they may show some improvement in their general functions. This has led Davidson and Girdwood to suggest that pteroylglutamic acid has two functions: to maintain normoblastic marrow action, and to control the behaviour of the alimentary tract.

The great difference between the sprue cases of American authors and those described in this country does suggest that the American patients may have had more gross nutritional deficiencies with superimposed gastro-intestinal disturbances, while the British ones are primarily due to a failure of absorption from the intestinal tract or else to a failure to utilize essential nutritional factors—in particular members of the vitamin B group.

While free folic acid itself is almost universally active in relation to bacterial growth and the relief of chick, animal, and human anaemias and certain rat leucopenias, this is not so with the so-called vitamin B₁₂ conjugates or pteroylglutamic acid conjugates. These conjugates consist essentially of pteroylglutamic acid combined with extra glutamic acid molecules to form polyglutamates, which are not universally active like the free folic or pteroylglutamic acid until the extra glutamic acid molecules have been removed by enzyme action or incubation with *Str. faecalis*. Nevertheless where they do act—as when given to rats, chicks, or monkeys suffering from *L. casei* factor, “vitamin B₁₂” deficiency, or “vitamin M” deficiency, respectively—their activities are proportional to their respective free folic acid contents.

The two crystalline polyglutamates so far examined are: (1) the vitamin B₁₂ conjugate prepared from yeast (pteroylhexaglutamyl-glutamic or pteroylheptaglutamic acid), which has no effect on the growth of *L. casei* and *Str. faecalis*, and (2) the fermentation or *L. casei* factor (pteroylglutamic acid conjugate), obtained by the extraction of certain corynebacteria residues as pteroyl-diglutamyl-glutamic (or pteroyl-triglutamic acid), which promotes the growth of *L. casei*, but is only 1/50 as active as *Str. faecalis*.

It has been suggested that patients with pernicious anaemia are able to utilize only free pteroylglutamic acid and not the polyglutamates, probably owing to the gastric deficiency (Bethell *et al.*, 1947; Heinle *et al.*, 1947), while patients with other macrocytic anaemias having normal gastric secretions could use the polyglutamates. Spies (1946a, 1946b) claims that the doses the above authors employed were too small, and he has obtained moderate haematological responses in pernicious anaemia using the natural polyglutamates and also one synthetic diglutamate. Others (e.g., Sharp *et al.*, 1947) have also obtained responses with natural conjugates. This requires further confirmation using synthetic conjugates, as it is of the greatest importance.

Chicks, dogs, rats, and monkeys apparently utilize the polyglutamates because the pteroylglutamic acid is liberated by certain enzymes present in their livers or kidneys and probably by enzymes or bacteria in their intestinal tracts. It is difficult to believe that the human organs behave so differently from these. In fact, Denko *et al.* (1946) have shown that folic acid can be synthesized in quite large amounts in the human gut.

Summary

The relationship of “folic acid” (pteroylglutamic acid) and the “folic acid conjugates” (pteroyltriglutamic and pteroylheptaglutamic acids) are considered with their effects on the haematological changes induced in chicks, rats, and monkeys.

The uses of synthetic pteroylglutamic acid in the oral and parenteral treatment of certain diseases involving the haemopoietic system in man are described.

Pteroylglutamic acid produces good haematological and clinical effects only in macrocytic anaemias with some degree of megaloblastic change in the bone marrows; it has little or no effect on patients with normoblastic marrows. Consequently the following anaemias respond to pteroylglutamic acid: pernicious anaemia; macrocytic megaloblastic anaemias of pregnancy, infancy, pellagra, sprue, steatorrhoea, and coeliac disease; nutritional macrocytic anaemias (with or without nutritional leucopenia), and possibly achrestic anaemia.

Pteroylglutamic acid acts equally well when given orally or parenterally and has no ill effects on the patient. The initial dose varies with the individual patient, but is usually 15–20 mg. a day orally, or 50–150 mg. intravenously.

In pernicious anaemia a prompt reticulocyte response is produced after the administration of pteroylglutamic acid, followed by general haematological and clinical improvement, but not

quite so well or so rapidly as with a highly potent liver extract. A maintenance treatment of 5–20 mg. daily is necessary, but after months of treatment a lower dose often shows a fall in the blood count and haemoglobin that will often respond to increased doses. Macrocytosis still tends to persist even after one to two years' treatment.

Pteroylglutamic acid is of no value in preventing the onset and progression or the development (which may be acute) of subacute combined degeneration of the cord in pernicious anaemia. For this reason it is not a satisfactory treatment for pernicious anaemia, and, since it has no advantages over present-day highly potent liver extracts or stomach preparations, it should not be given alone as routine to patients with pernicious anaemia.

Refractory macrocytic normoblastic anaemias do not respond to pteroylglutamic acid, but refractory megaloblastic anaemia may give responses.

It often relieves the symptoms of the sprue syndrome, leading to better-formed stools and some improvement in blood count, but only in the megaloblastic cases: the responses are irregular in steatorrhoea, and liver extracts may be required additionally to produce complete remissions. The response in coeliac disease may be very slow or poor; those with normoblastic marrows do not respond, since pteroylglutamic acid is effective only where megaloblastic erythropoiesis is present.

Pteroylglutamic acid has no beneficial clinical or haematological effects on hypochromic microcytic anaemias, haemolytic anaemias, refractory megalocytic anaemias with normoblastic marrows, acute and chronic leukaemias of all types, leucocythroblastic anaemia, chronic ulcerative colitis, anaemias secondary to myxoedema or hyperthyroidism, toxic or idiopathic aplastic and hypoplastic anaemias, agranulocytosis, neutropenias, and thrombocytopenic purpura, but it relieves leucopenia and thrombocytopenia when these are features of a nutritional deficiency or a megaloblastic anaemia.

There is no place in therapeutics for the “blunderbuss” preparations of pteroylglutamic acid plus iron, liver extract, etc.

Pteroylglutamic acid is not the extrinsic factor, haemopoietin (the stomach enzyme or intrinsic factor), or the liver anti-pernicious-anaemia principle, nor is it the possible “neuro-poietic” principle (anti-subacute combined degeneration of the cord). The effects of pteroylglutamic acid on haemopoiesis are discussed.

There may possibly be a separate factor in liver and hog's stomach preparations with neuropoietic properties for preventing or curing the neurological symptoms in pernicious anaemia.

The anti-pernicious-anaemia potencies of substances related to pteroylglutamic acid are considered.

CONGENITAL MEGACOLON

RESULTS OF TREATMENT BY SPINAL ANAESTHESIA

BY

E. D. TELFORD, F.R.C.S.

Emeritus Professor of Surgery,
University of Manchester

AND

H. A. HAXTON, M.D., Ch.M., F.R.C.S.

Research Fellow, Manchester Royal Infirmary

In the milder cases of megacolon in childhood it may be that diet and medical measures will secure a sufficient action of the bowel, but where diet and drugs alike fail and frequent recourse has to be had to enemata and mechanical evacuation the need for surgical treatment is clear. Without such treatment the trouble tends to worsen, and in the more severe forms death is likely before the age of 20.

The fashion of surgical intervention has changed from time to time. In earlier days short-circuiting operations were tried and found wanting, while heroic resections of the dilated colon were attended by a high mortality even in experienced hands: 25% by Adson (1937). The mortality should certainly be lower to-day as a result of the better pre-operative preparation of the patient and his colon. There is undoubtedly a place for resection in the most severe varieties of the trouble which show no response to other forms of treatment.

The conception that megacolon is due to an achalasia—i.e., an imbalance between the sympathetic (filling) and the parasympathetic (emptying) mechanism which results in a relative inadequacy of the latter action—at once altered the outlook by suggesting an attack on the nerve supply rather than on the bowel itself. The sympathetic supply was interrupted in various places by bilateral lumbar, unilateral lumbar, presacral, and inferior mesenteric sympathectomies. On the whole, good results were obtained at small risk. But in 1935 Stabins, Morton, and Scott showed that success followed the use of a spinal anaesthetic alone. Since that date a number of successful results have been reported by various workers. These reports are open to criticism in that the follow-up period is too short. We have therefore re-examined those patients who were treated by spinal anaesthesia in the neurovascular clinic of the Manchester Royal Infirmary between the years 1938 and 1945. Cases treated within the last two years have been rejected as being too recent to be included.

The number of patients treated during the period is 17. We saw 11 of these patients during December, 1947, and obtained a detailed account of another: five were not traced. These 12 children comprised seven boys and five girls. The youngest was aged 6 months and the oldest 13 years when treated. The average age of the group was 7 years.

Technique

Apart from considerations of safety and control, the drug and method used for the spinal anaesthetic are immaterial. The point is that the effect must reach as high as the anterior roots of T.5 in order to abolish all activity in the splanchnic nerves. To make sure of this it is usual to allow the level of the anaesthesia to rise to the third thoracic segment or even higher, until tingling is felt on the inner side of the hand (T.1). The state of relaxation of the rectus abdominis is a good guide to the paralysis of the anterior roots; the muscle should be flaccid throughout so that the epigastrium bulges when the child cries or coughs.

After-treatment is important, and we have found the following regime to be satisfactory. Liquid paraffin is given daily in one dose of 1/2 oz. (14 ml.), and the enemata are administered every second day during the first week, twice during the second week, and once during the third. Enemata are then discontinued, but liquid paraffin is given in gradually reduced doses for as long as may seem necessary.

Results

The result has been classified as "good" in cases where the bowel action has become normal, "fair" when a considerable improvement has resulted but medicine is still required to maintain regular action, and "failed" when no worth-while improvement has been seen. The 12 cases are grouped as follows: good 8, fair 2, failed 2.

These cases were of a severe type and showed intractable constipation, physical under-development, "pie-crust" complexion, and mental lethargy—all features which mark the more serious forms of the disease. In the successful cases the parents have noticed that the children become much more energetic physically and much brighter mentally, often taking a better place at school. The improvement in growth, in development, and in complexion is striking to the observer. Four of the eight cured cases were treated not less than nine years before, and over this long period their bowel action has remained normal and unaltered.

Lumbar sympathectomy was done in three of the four unsatisfactory cases from one to two years after the spinal anaesthesia, but in only one of these did any further improvement result. It seems likely that cases in which a spinal anaesthetic has failed to produce improvement will also prove refractory to sympathectomy.

Discussion

The explanation of the results obtained in the megacolon of childhood from spinal anaesthesia remains a mystery, and the method must at present be regarded as purely empirical. For some reason the shock of the anaesthetic abolishes the imbalance between the sympathetic and parasympathetic supply of the colon. One can only assert that the method is simple and that it works. We believe that good results are more certain in the younger patients, and that 12 years would seem to be the upper age limit for success. The method is useless in the megacolon of adults, usually mechanical in origin, and in cases of ptosis with constipation in young women.

It is worth while to remember that in cases of megacolon the intra-abdominal scybalous mass, together with the general ill-health and malnutrition, may suggest a diagnosis of tuberculous mesenterica. In fact, of the present series no fewer than four were salvaged from sanatoria.

Finally, we must emphasize that there may be a delay of several weeks after the administration of the spinal anaesthetic before any improvement is manifest. Failure to recognize this has doubtless been the cause of the supposedly good results which some have had with the method. Later

follow-up is likely to reveal a great improvement of which there was no sign during the stay in hospital (Hawksley, 1944).

Summary

The late results of cases of megacolon treated with spinal anaesthesia from two to nine years previously are reported. Out of 12 cases eight were found to remain fully cured.

MEGALOBlastic ANAEMIA OF PREGNANCY

REPORT OF AN UNUSUAL CASE

BY

M. GILLESPIE, M.D.

AND

A. M. RAMSAY, M.D.

(From the L.C.C. Group Laboratory and North-Western
Fever Hospital, Hampstead)

In recent years considerable attention has been paid to macrocytic anaemia of pregnancy. In 1938 Stevenson reported a series of 30 cases, and since then over 80 cases have been described by other investigators in this country (Davidson, Davis, and Innes, 1942; Lescher, 1942; Miller and Studdert, 1942; Fullerton, 1943; Callender, 1944). The term "megaloblastic anaemia of pregnancy" was suggested by Davidson, Davis, and Innes (1942) to replace "pernicious anaemia of pregnancy," since many of the criteria of true Addison's anaemia were not found in their cases. Callender (1944), while emphasizing the variability of the findings in this disease, considered two necessary diagnostic features to be "the presence of true megaloblasts in the peripheral blood and the demonstration of a megaloblastic change in the bone marrow."

The case reported below presents features which we have not been able to find in the literature and which we consider make it worthy of publication.

Case Report

A primipara aged 21 was delivered on Nov. 25, 1946, of a healthy female infant at an L.C.C. hospital. There was a second-degree primary tear, which was sutured. The antenatal history was negative, except that the patient was pale throughout pregnancy and had a persistent cough. She became pyrexial on Nov. 26; sulphadiazine and penicillin were given, but pyrexia continued. The haemoglobin on the 27th was 41%. She was transferred to the North-Western Hospital puerperal sepsis unit on Nov. 29.

On admission she was very pale and had a septic second-degree tear of the perineum, with a septic and lacerated cervix, but a normally involuting uterus. The spleen was palpable. Cultures from the cervix yielded no significant growth, and urine and blood cultures were sterile. A blood count (see Table I) showed marked anaemia, and she was transfused slowly with 1 litre of blood. The blood count, however, showed no improvement after the transfusion. Sternal puncture was performed on Dec. 3. In spite of penicillin treatment (30,000 units three-hourly) pyrexia persisted and numerous small pustules developed on the wrists and arms. Later, retinal haemorrhages occurred. Intensive liver treatment was started on Dec. 13, and a further blood transfusion was given with but little effect. The patient died suddenly on Dec. 31.

Haematological Findings

The first blood count on Nov. 30 showed a profound anaemia (haemoglobin 35%), and the white blood cells were decreased, with a high proportion of immature granulocytes. As the

patient had sulphadiazine before admission it was thought that the drug might have depressed granulocyte production. When, however, the blood showed no improvement after transfusion and the white cells became more immature the possibility of acute leukaemia was suggested and sternal puncture was performed with the following results:

Total nucleated cells 89,000 per cmm

	N	E	B.
Polymorphs	5	—	—
Metamyelocytes	2	—	—
Myelocytes	20	—	—
Promyelocytes	7	—	—
Myeloblasts	22	—	—
Lymphocytes	5	—	—
Normoblasts, late	12	—	—
Normoblasts, intermediate	10	—	—
Normoblasts, early	2	—	—
Megaloblasts, late	8	—	—
Megaloblasts, intermediate	2	—	—
Megaloblasts, early	4	—	—
Proerythroblasts	0	—	—

Myeloid/erythroblast ratio = 1.5:1

Since these findings did not confirm the diagnosis of leukaemia, and in view of the high erythroblast ratio with the presence of megaloblasts, a tentative diagnosis of liver-deficiency anaemia with coincident failure of maturation of the granular series was made. Intramuscular injections of "neohepatex," 4 ml. daily, were given, but after seven days the reticulocytes were only 11% (i.e., about one-third of the expected response) and the red blood cells and haemoglobin showed a continuous slight fall (see Chart). Nucleated red blood cells rose from 30

per 100 white blood cells before treatment to 170 per 100 white blood cells at the peak of the reticulocyte crisis (see Table II). There was no reduction in platelets during the period of observation. After 10 days' treatment the red blood cells had fallen to 800,000 per cmm. and haemoglobin to 18%. A second transfusion of 500 ml. of blood was given, and neohepatex was replaced by proteolysed liver, 7 ml. daily by mouth (Davis and Davidson, 1944). The proteolysed liver appeared to be less effective than the neohepatex. Accordingly a single dose of

hepatex, 10 ml., was injected intramuscularly and this was followed by 4 ml. of neohepatex daily. There was no response, however, to either preparation before the sudden death of the patient.

TABLE II—Differential Nucleated Red Count

Post-mortem Findings

Permission for necropsy was not granted till 48 hours after death, and post-mortem change was advanced in all organs. There was caseous tuberculosis of the hilar glands and a caseous tuberculous focus, 1 cm. in diameter, in the lower lobe of the right lung. The heart muscle was thin, pale, and flabby, with a few subpericardial haemorrhages. The spleen (450 g.) was congested and friable. The liver (3,000 g.) was pale and rather greasy. The uterus showed some necrosis of the placental site but was well involuted. Apart from generalized pallor there was little of pathological importance in the other organs. The bone marrow of the sternum, ribs, and femur was a rich dark-red colour. Sections and films of sternal marrow showed an extreme cellularity, the predominant cell being of the primitive haemocytoblast variety with large numbers of megaloblasts (mostly early) and normoblasts. Granulocytes and their precursors were almost completely absent. Megakaryocytes were numerous. As the patient died unexpectedly in the evening and marrow puncture was not done till next day, the cells were somewhat degenerate.

Discussion

In the various reports of cases already quoted little mention is made of any changes in the white blood cells. Callender (1944) found a leucopenia common with "myelocytes and young forms." Other writers record low total white blood cells but give no differential counts. We have been unable to find any reference to such profound immaturity of the white blood cells in the peripheral blood in any other cases of megaloblastic anaemia of pregnancy, although myeloblasts are occasionally found in the peripheral blood in pernicious anaemia (Whitby and Britton, 1946). In our patient leucopenia was constant and the white blood cells decreased gradually from 5,000 to 1,500 per cmm. the day before death. Myelocytes,

promyelocytes, and myeloblasts formed from about 20 to 50% of the total for the first two weeks, gradually falling with the count (Table I). It has already been mentioned that the question of agranulocytosis following sulphadiazine was raised after the first count. In our experience, however, it is unusual to find early granulocytes in the peripheral blood in agranulocytosis except during recovery. Generally the polymorphs drop suddenly without warning, and no precursors reach the peripheral blood until regeneration of the marrow is taking place. In this case, also, only 8 g. of sulphadiazine had been given. The alternative suggestion of acute leukaemia appeared at first to fit the severe anaemia with myeloblasts in the peripheral blood, but sternal puncture did not confirm this. The findings of a definite megaloblastic reaction in the marrow suggested rather a deficiency of the haemopoietic principle, and it seemed probable that this was the primary abnormality and that the high proportion of myeloblasts was due to a coincident failure of maturation of the granulocytes rather than a true leukaemic change.

Although liver therapy was not begun until a late stage in the disease, the poor response to the three preparations used seems to indicate the refractory nature of the anaemia. Defective absorption from the intestine may have been partly responsible for producing the anaemia, since proteolysed liver was even less effective than neohepatex. Nutritional deficiency might also account for the failure in maturation of the granulocytes.

Summary

A case of megaloblastic anaemia of pregnancy is described.

An unusual feature was the marked immaturity of the circulating granulocytes simulating an acute myeloblastic leukaemia.

The case proved refractory to various types of liver therapy and to blood transfusion.

ADDENDUM

Since the completion of this paper, blood and sternal marrow films were referred to one of us (M.G.) from another L.C.C. hospital for diagnosis. The patient, a married woman aged 34, had been treated by her doctor for acute tonsillitis and various other complaints with 70 g. of a sulphonamide over a period of five weeks. On admission she complained of giddiness and faintness of two weeks' duration, and her blood count on Dec. 8, 1947, was: red blood cells, 1,000,000 per c.mm.; haemoglobin (Sahli), 24%; colour index, 1.2; white blood cells, 13,000 per c.mm. (neutrophil polymorphs 9%, promyelocytes 77%, myeloblasts 14%); mean cell diameter 7.8 μ ; nucleated red blood cells, 21 per 100 white blood cells (normoblasts 15, megaloblasts 6); anisocytosis + +, poikilocytosis +, polychromasia + +.

The patient was transfused with 2 pints (1.14 litres) of blood, and on Dec. 10 the sternal marrow films showed the following distribution:

Neutrophil polymorphs	1.5%
Metamyelocytes	0.0%
Myelocytes	0.5%
Promyelocytes	30.0%
Myeloblasts	11.0%
Lymphocytes	4.0%
Normoblasts, late	7.5%
" intermediate	2.5%
" early	0.0%
Megaloblasts, late	11.5%
" intermediate	20.0%
" early	9.5%
Proerythroblasts	2.0%

Myeloid/erythroblast ratio = 1:1.2

Since both the peripheral blood and marrow resembled the case described above the patient was treated with liver and iron but showed no reticulocyte response. After two further transfusions on Dec. 12 and 17 her red blood cells rose to 3,800,000 per c.mm. and haemoglobin to 73%. Although she was given penicillin throughout her stay in hospital she developed pneumonia on Dec. 19 with Friedländer's bacillus and *Ps. pyocyanea* in the sputum. The blood count was maintained without

further transfusion and the white cells, which had dropped to 750 per c.mm. on Dec. 20, rose to 9,000 per c.mm. on the 24th, with a much lower percentage of primitive cells. The patient died on Dec. 25. Post-mortem examination showed bronchopneumonia and an extremely cellular bone marrow. Sections showed the majority of cells to be of the red cell series and apparently megaloblastic.

The similarity between the two cases is striking. Both showed extreme anaemia with megaloblasts and primitive white cells in the peripheral blood and a megaloblastic reaction in the marrow, and both failed to respond to liver. Aetiologically, however, the two cases differed: in the first case pregnancy, and in the second the excessive dosage of sulphonamide, were apparently the main contributory factors.

We are indebted to Dr. R. D. Green, of Paddington Hospital, for the clinical notes of the second case.

HEREDITARY OEDEMA (MILROY'S DISEASE)

BY

J. BRAHAM, M.C., M.D.

Medical Registrar, St. James's Hospital, Leeds

AND

G. HOWELLS, M.B., B.S.

Reports on a heredo-familial variety of oedema of the lower limbs were published almost simultaneously by Nonne (1891) and Milroy (1892). A few years later Meige (1899) reported a further series of cases. The condition described as hereditary oedema, or eponymously as Milroy-Nonne-Meige disease, has since been recognized as a distinct clinical entity, having been recorded by many physicians in various countries. References in British literature have, however, been relatively scanty, the only one in recent years being that of Weber and Schlüter (1937). The main features of Milroy's disease are here summarized.

Aetiology.—The disease is hereditary. Milroy's original family of 97 persons in six generations presented 22 cases. Meige reported eight cases in four generations, Hope and French (1907) 13 cases in five generations of 42 persons. Gates (1946), analysing the family described by Hope and French, considers the hereditary trait to be a Mendelian dominant, but notes that in one affected person it was transmitted through an apparently normal mother. Two unaffected mothers in the third generation of Milroy's family passed the tendency on to some of their offspring. Such a skipping of a generation is common in human dominant pedigrees. Both sexes are affected. The cause of the oedema is not known; it is not related to the usual general or local causes of oedema, such as cardiac or renal disease, venous or lymphatic obstruction. Meige postulated a "congenital malformation of trophic centres in the spinal cord," though this has never been proved. Hope and French compare the disease with other heredo-familial disorders of the vasomotor system, such as angioneurotic oedema, Raynaud's phenomenon, and urticaria, and suggest that it may be a "vasomotor neurosis." Milroy (1928), in a review of the condition.

agrees with this point of view, favouring a local cause, such as an abnormality of function of veins or lymphatics, of neurogenic origin.

Pathology.—A necropsy has not yet been recorded on a case of Milroy's disease, and the only microscopical study which appears in the literature is that of McGuire and Zeek (1932), who report the results of biopsy in a typical case. Microscopy of a portion of the skin and subcutaneous tissue showed a normal epidermis but a marked condensation of the superficial portion of the dermal papillary layer composed of fine collagen fibrils which in some places were undergoing hyalinization; oedema was more pronounced in the dermis, and this, together with an increase of collagen fibres, produced a great increase in the proportion of dermis to epidermis. There was a considerable sprinkling of lymphocytes related to the capillaries and venules. The subcutaneous tissue was also thickened, consisting of masses of oedematous fatty tissue and pools of colourless fluid not contained within definite limiting boundaries. The appearance contrasted with that of fresh necropsy material obtained from cases of cardiac and renal dropsy: in these the dermal papillae were flattened and much less obvious.

Clinical Features.—The age of onset varies in the different families recorded. In Milroy's series all but two showed oedema at birth. In one of these the oedema started at the age of 12; in the other, one swollen foot was present at birth, the other limb being normal until the age of 20, when, following an injury, it became rapidly and permanently swollen. All of Meigs's cases had their onset at puberty. In the family recorded by Hope and French (1907) oedema began in infancy, childhood, or adolescence. As each author has described a single family, differences in age of onset and other features may, as Milroy (1928) pointed out, be considered to be familial variations of an essentially identical disorder.

The oedema begins in the foot, gradually spreads up the limb, but never extends above the level of the inguinal ligament, where it is sharply demarcated; it may remain at lower levels, especially joints, for long periods. At first the oedema pits readily on pressure, though later the tissues become more indurated and thickened, and is reduced by rest with elevation of the limb. One or both limbs may be affected. There are no constitutional disturbances and the disorder is compatible with long life. Another remarkable feature of the condition is the absence of disability: in spite of grossly swollen limbs affected persons may be quite capable of a normal existence. One of Milroy's (1928) patients was a Burma missionary who wrote that he found no difficulty in tramping distances of 30 miles a day over rough mountain track. The oedema appears to be permanent, with the remarkable exception of another of the cases mentioned by Milroy (1892) (unfortunately not seen by Milroy himself). This patient was born with oedema of one foot, and at puberty developed swelling of the testicles which became sufficiently great to necessitate orchidectomy, and at the same time the swelling of the foot disappeared.

In addition to the above clinical features Hope and French (1907) described acute attacks in many of their patients in which the affected limbs suddenly became red, painful, tender, and much more swollen; there was no obvious cause for the onset or remissions of these attacks.

Treatment.—Because of the minimal symptoms there is usually no indication of any treatment other than bandaging to control the size of the limb. Among patients with oedema of the limb treated by the Kondoleon operation Sistrunk (1918) records two cases with oedema of the lower limb in which the clinical histories suggest a diagnosis of Milroy's disease; good results were obtained, and this suggests that surgery may be useful if there is serious disability.

Case Report

An apprentice engineer aged 19 was referred by Dr. Hugh Garland from his out-patient clinic at the General Infirmary at Leeds and admitted to St. James's Hospital, Leeds, complaining of swelling of his right leg and his scrotum. He had had no previous major illness. There was no history of "allergic" disease or of infection in the legs. He had never been out of this country.

Family History.—The patient was the youngest of three children. His parents were not blood relatives. His elder sister, a housewife aged 24, had noticed swelling of her right leg when she was 14. Up to the age of 20 she had worked in a factory and the swelling was then severe at the end of the day, and at its worst had extended from ankle to knee. When seen by us the left leg appeared normal, the right leg showed a pitting oedema involving the ankle and the lower third of the right calf. There was no other evidence of disease of any kind. She had had no children. The younger sister, a housewife aged 22, had no history of oedema and no abnormality on examination. She had one child, a boy aged 2, with no abnormality. The father, aged 52, had no abnormality on examination. The mother, aged 45, one of twelve siblings, though showing no abnormality of the lower limbs on examination, herself asserted that since puberty she had noticed her ankles to be swollen at the end of a day's work. No history was obtained of any oedema of the limbs in preceding generations on either side, nor was there any history of familial disease.

History of Illness.—The patient first noticed swelling of his right ankle at the age of 17, which was painless and decreased at night after rest. It had gradually and steadily increased, spreading upwards to involve the whole of the leg. He had also noticed swelling of the scrotum, which he thought had begun at about the time the leg swelling had reached the groin. He thought the condition had been stationary for the four months before admission. Despite the size of the leg there had been little interference with function and he led a normal life. He had had no acute exacerbation of the condition, nor anything suggestive of infection in the leg. It seems that puberty had not been reached until the age of 17 and had roughly coincided with the onset of the oedema. He was shaving only once a week at 19.

On examination he was a slimly built youth who looked younger than his age. There was little facial, axillary, or pubic hair. The left leg was normal. There was massive pitting oedema of the right leg, sharply limited above by the inguinal ligament and fading towards the toes, which appeared normal when first seen. The colour and temperature of the limb were normal. There were no trophic disturbances of the skin and no enlarged veins. After he had worn slippers for two days the oedema spread into the toes. The scrotum was not oedematous. There was bilateral hydrocele, left larger than right. After the hydroceles were tapped the testicles were found to be bilaterally and symmetrically enlarged, and testicular sensation was much diminished. After complete rest in bed the oedema decreased steadily, the minimum size being reached in five days; it increased to its maximum in three days when the patient was allowed up again. (See illustration.)

Measurements

	On Admission				After 5 Days at Rest			
	Right		Left		Right		Left	
Mid-foot ..	in. 10	cm. 25.4	in. 9	cm. 22.8	in. 8	cm. 22.3	in. 9	cm. 22.8
Ankle ..	12	31.75	9	22.8	9	22.8	9	22.8
Calf 4 in. (10 cm.) below patella ..	16	41.9	12	30.5	13	34.5	12	30.5
Mid-thigh ..	20	52.0	16	40.6	17	44.5	16	40.6

Laboratory Tests.—Haemoglobin, 108%; leucocytes, 6,500 per c.mm. (44% polymorphs, 52% lymphocytes, 4% monocytes). Blood potassium, 21.2 mg. per 100 ml.; blood urea, 19 mg. per 100 ml.; serum protein, 7.7%; chlorides (as NaCl), 0.57%; creatinine, 1.7 mg. per 100 ml.; uric acid, 4 mg. per 100 ml. Glucose-tolerance test normal. Urine: S.G. 1026, acid; no albumin, sugar, casts, or cells. Urinary chlorides, 7.4 g. in 24 hours. Fractional test meal, normal curve. Histamine

skin sensitivity test, no reaction. Radiograph of bones normal. Wassermann reaction negative.

Treatment.—The patient suffered very little disability from his oedema and was quite able to enjoy a normal life. He complained of some "tiredness" of the affected limb at the

end of the day, but despite this he would voluntarily indulge in gymnastic exercises after a full day's work. No surgical intervention was therefore advised. Firm bandaging had some effect in controlling the oedema and also gave him a feeling of support.

Discussion

Examples of unilateral or bilateral oedema of the extremities for which no obvious cause can be discovered are not infrequently encountered; cases with a clear hereditary or family history are, however, much less common, and few have been recorded in British medical literature. The question arises whether patients who display the typical oedema of one or both lower limbs as described above, but who lack the appropriate family history, should be regarded as suffering from Milroy's disease. In this connexion we note that Parkes Weber, discussing at a meeting of the Royal Society of Medicine a family of four sisters in whom oedema of the legs began between the ages of 20 and 23 (Weber and Schlüter, 1937), considered that if the other features were present a family history was not essential for the diagnosis, and for that reason preferred the eponym Nonne-Milroy's disease to the term hereditary oedema. However, the heredo-familial factor in the classical descriptions quoted above is so striking that it seems to justify a separate nomenclature for the hereditary and non-hereditary forms. In describing the aetiological factors it was noted that one unaffected person in the family reported by Hope and French (1907) and two unaffected persons in the family reported by Milroy (1892) produced affected offspring. Apart from these gaps, however, the line of inheritance is direct. It appears, therefore, that the responsible gene is transmitted as a Mendelian dominant with occa-

sional skipping of a generation. In view of this possibility of skipping, the fact that the disease has been recognized for the first time in members of a particular generation does not rule out the likelihood that it has been handed down from earlier generations, especially when it is remembered that the manifestations may be minimal, easily missed by patient and doctor. (In the families described above there was considerable case variation in the degree of oedema, and this was also found in the family reported by us.) Alternatively the condition may arise as a mutation, though this is impossible to establish.

Apart from the description by Milroy (1892) of the patient with testicular enlargement and subsequent disappearance of the oedema, we have not discovered any record of a patient who, like the one we have reported, suffered also from hydrocele and testicular abnormality. While there seemed to be definite evidence of diminished testicular function, it is not clear that there was any relation between this and the oedema, nor would it justify in itself any suggestion that an endocrine factor plays a part in the production of the oedema. Although the disorder has been recognized for over fifty years, the ultimate mechanisms responsible for the chief symptoms remain obscure.

Summary

Milroy described a hereditary form of oedema of the lower limbs for which there was no obvious cause.

This condition produces little or no disability.

A typical case, with bilateral hydrocele and delayed puberty, is described.

We wish to acknowledge our thanks to Dr. Hugh Garland, consulting physician to St. James's Hospital, and to Dr. J. A. Fraser Roberts for much helpful advice and criticism. Dr. W. McIntosh, Medical Director of Leeds Municipal General Hospitals, kindly granted permission to publish this case. Our thanks are also due to Miss C. E. Campbell for the photograph.

TWO CASES OF PERIARTERITIS NODOSA WITH OBSERVATIONS ON AETIOLOGY, DIAGNOSIS, AND TREATMENT

BY

JOHN M. SUTHERLAND, M.B., Ch.B.

Periarteritis nodosa was first described by Rokitsansky in 1852. Kussmaul in 1866 related symptomatology to clinical findings, and during the next 76 years some 350 cases of the disease were reported. Here are recorded two further cases.

Case 1

This patient, a Merchant Navy man, aged 43, was admitted to the Western Infirmary, Glasgow, on Oct. 20, 1946. He complained of an aching pain in the muscles of his back and legs, epigastric discomfort, anorexia, and loss of weight for four weeks. This had been associated with a low-grade pyrexia. He had had malaria in 1938, and in 1939 was treated for staphylococcal empyema by rib-resection and with sulphapyridine over a long period. Sulphonamides had also been administered three weeks and again three days before admission to the infirmary.

On admission the abdomen showed slight generalized distension. It was "doughy," and on palpation the epigastrium and

both lumbar regions were tender and rigid. The muscles of the legs were tender on pressure; no oedema was observed. No other physical abnormality was detected. Temperature was 99.2° F. (37.3° C.), pulse 105, and blood pressure 150/90. During the next 17 days his condition deteriorated. The temperature was intermittent, ranging from 97 to 101.5° F. (36.1 to 38.6° C.). The pulse rate varied from 80 to 115. Muscular and abdominal pains and increasing general weakness accompanied these changes. On Nov. 8, and for several days subsequently, painful subcutaneous nodules were present on the abdominal wall. One such nodule was removed for histological examination.

After Nov. 15 his general condition improved, although two further exacerbations occurred. On Nov. 22 he complained of stiffness of the neck muscles and pain in the right testicle. On Nov. 19 pain in the lower left chest and left hypochondrium was accompanied by splenic enlargement. During this time the temperature continued to range between 97 and 101° F., and the pulse rate between 70 and 120. The erythrocyte sedimentation rate varied between 37:70 and 75:106 (Westergren).

These acute manifestations subsided within a few days, and the patient continued to improve generally. On Jan. 11, 1947, he was afebrile and symptom-free, and was discharged from hospital.

Investigations in Hospital.—**Blood.**—There was no evidence of anaemia. The white cell count varied from 27,200 to 11,000 per c.mm. The highest eosinophil reading reported was 5%. On Dec. 6 the serum albumin was estimated at 4.6% and total protein at 6.4%. The Wassermann reaction was negative. **Urine.**—No abnormal constituents were found. Despite repeated investigations, tests for albumin and red blood cells were uniformly negative. **Fractional test meal.**—A normal acid curve was obtained. Blood was present in the fasting juice, and a test for occult blood in the faeces was positive. **X-ray examination.**—Radiologically the lumbar spine, gall-bladder, chest, and arms revealed no abnormal features. Barium meal and enema investigation of stomach and bowel did not disclose any evidence of disease. **Ophthalmoscopic examination** (Nov. 23).—Prof W. J. B. Riddell reported that no abnormality was detected in either fundus. **An electrocardiogram** (Nov. 23) showed slurring of QRS in leads I and III of a degree which is proof of myocardial change. **Proctoscopic examination** (Dec. 12) revealed no marked change in rectal mucosa. Excess mucus coming down from sigmoid was present; examination of this showed no abnormality. **Histology of subcutaneous nodule** (Nov. 14).—The report on the subcutaneous nodule removed from the abdominal wall was furnished by Dr. G. B. S. Roberts. It read: "The larger blood vessels show changes characteristic of periarteritis nodosa. There is fibrin present in the media and a gross collection of inflammatory cells, mainly polymorphs, in the adventitia."

Progress since Discharge from Hospital.—Since the patient was discharged from hospital (Jan. 11, 1947) three episodes of significance have occurred. (1) On Jan. 24 the patient's urine contained albumin, red blood cells, and granular casts. (2) On March 21 the patient complained of severe headaches, maximal in intensity over the vertex. On March 25 retinal haemorrhage in the left eye was reported, and on April 15 it was suggested that a further haemorrhage had occurred and that the vessel associated with this haemorrhage was raised from the retina. (3) On March 27 he complained of the passage of blood in his stools. This complaint persisted for three weeks. Further proctoscopic examination did not reveal any abnormal feature with the exception of a congested rectal mucosa. No specific pathogenic micro-organisms were isolated from a rectal swab. Bleeding time, clotting time, and blood film were within normal limits.

During this period of out-patient surveillance the condition of the myocardium improved, as shown by repeated electrocardiographic tracings. On Feb. 28 the electrocardiogram showed that slurring of QRS was not then of diagnostic significance.

Comment on Case 1.—The two main points of interest are: (1) the diagnosis was made during life, and (2) some thirteen months after discharge the patient is well enough to be in employment. The average duration of the disease

is given by Leishman (1937) as between three and four months. Some cases, however, have been known to recover.

Case 2

A housekeeper aged 52 was admitted to the Western Infirmary, Glasgow, on Dec. 13, 1946, with a complaint of pain in the chest and haemoptysis of ten days' duration and loss of weight and general weakness for some nine months.

Previous History.—She had been under investigation in a county hospital from July to November, 1946. The history and investigations covering this part of her illness were as follows. Subsequent to an influenzal illness occurring over Christmas, 1945, she experienced weakness of her legs associated with pain in legs, arms, and back of neck. No sulphonamide drugs were given at this time. Her left ankle is stated to have been swollen, and anorexia was accompanied by considerable loss of weight. Clinical examination seems to have been largely negative. "Fibrous" nodules were reported to be present in the trapezius. Blood pressure was 120/80. The temperature varied between 97 and 101.5° F. (36.1 and 38.6° C.) and the pulse rate between 80 and 120, until mid-September, 1946, when both gradually settled to average levels. This was maintained until she was discharged on Nov. 9. The erythrocyte sedimentation rate remained elevated throughout this period—July, 93:115; October, 92:120. The following investigations were carried out: (1) **Blood.**—No evidence of anaemia present. The leucocyte count varied between 5,000 and 11,500 per c.mm. The highest eosinophil reading reported was 2%. (2) **Urine.**—Reaction acid; specific gravity, 1026. Albumin, trace. On microscopic examination 8 to 11 red blood cells were present per high-power field. (3) **Fractional test meal.**—A normal free-acid curve was obtained. A test for occult blood in the faeces was positive. (4) **X-ray examination** of chest, long bones, hands, and feet, barium meal, and barium enema revealed no gross lesions.

After being discharged home on Nov. 9, 1946, the patient remained in moderately good health until three weeks before admission to the Western Infirmary. At this time she developed herpes zoster of her right chest, and after a few days haemoptysis occurred. Recurrent vomiting was complained of for six days before admission to the infirmary.

On admission the patient looked very ill and was markedly emaciated. The percussion note over the right apex was impaired, and crepitant rales were present at the right apex, right mid-zone, and left base. The abdominal reflexes were not elicited; both ankle- and knee-jerks were very active; the plantar responses were flexor. The pulse rate varied between 80 and 120, the temperature between 97 and 98° F. (36.1 and 36.7° C.). The blood pressure was 118/75. The patient is stated to have suffered from "chest trouble" in adolescence. Her mother died of "chest trouble." Her father died of rheumatic fever at the age of 27.

A blood count showed: red cells, 2,100,000 per c.mm.; haemoglobin, 47%; white cells, 8,000 per c.mm. The erythrocyte sedimentation rate was 120:150. No abnormality was detected in the urine. Tubercle bacilli were not found in the sputum. An x-ray report of the chest on Dec. 13 was: "Old calcified primary lesions in both hilar regions and in right lower lobe. Mottled opacities right upper lobe. Appearances are suggestive of active tuberculosis. There is increase in transverse diameter of the heart."

On Dec. 17, four days after admission, the patient died suddenly.

Post-mortem Report.—A necropsy carried out by Dr. George Smith in the pathology department disclosed the presence of typical lesions of periarteritis nodosa in kidneys, liver, lungs, spleen, heart, small intestines, pancreas, adrenals, and uterus. While a few of the lesions were reported to be in the healing phase of fibrosis the great majority showed acute necrotising inflammation of the vessel wall with oedema and polymorph infiltration, in which eosinophils were noteworthy. The vessels chiefly affected were the small arteries and arterioles. With the exception of a healed calcified scar at the apex of the left lung no evidence of pulmonary tuberculosis was detected. Both lungs were denser in patches than normal, but the consistency was considered to be not that of fibrosis or neoplasm.

and was due to haemorrhage. Histological examination did not disclose the presence of tuberculous lesions in the lungs. The immediate cause of death was probably the severe damage to the kidneys. The femoral vein blood urea twelve hours after death was 129 mg. per 100 ml.

Comment on Case 2.—This case was not diagnosed until a post-mortem examination had been performed. The clinical diagnosis appeared to rest between pulmonary neoplasm and pulmonary tuberculosis. The latter possibility was supported by the result of x-ray examination of the chest, to which reference has been made. The interesting points in the case are: (1) The patient was a female suffering from a rare disease in which males are affected four times as often as females. (2) Haemoptysis is not a common symptom of periarteritis nodosa. It occurred in only 1% of cases in a series reviewed by Bruce Logue and Mullins (1946). (3) In Kline and Young's (1934) three cases the difficulty in differentiating periarteritis nodosa affecting the lungs from pulmonary tuberculosis was observed. Bruce Logue and Mullins (1946), referring to this, suggest that areas of fibrosis due to small infarctions may resemble pulmonary tuberculosis radiologically. In this case the findings both on clinical and on x-ray examination were compatible with a diagnosis of pulmonary tuberculosis.

Aetiology

The cause of periarteritis nodosa is not yet definitely known. Transmission of the disease to animals has been reported by Von Haun (1920) and by Harris and Friedrichs (1922). These results do not appear to have been obtained by other workers, although Muir (1940) considers the pathological picture to be compatible with the activity of an unknown infective agent.

Ophills (1923) and Neale and Whitfield (1934) suggest that periarteritis nodosa is a manifestation of a streptococcal allergic state. Its association with rheumatic heart disease was noted by Friedberg and Cross (1934) in four of their eight cases, and they considered that the disease may result from hypersensitivity to more than one agent. This view has received the support of Anderson (1944). Eight cases of periarteritis nodosa associated with asthma and eosinophilia are reported by Rackemann and Greene (1939), and Rich (1942) records the development of periarteritis nodosa in cases which had shown evidence of hypersensitivity to serum or sulphonamides, or both. In 1943 Rich and Gregory demonstrated that the disease could be produced experimentally in rabbits by sensitizing them to foreign serum-sulphonamide complexes. In 1946 Bruce Logue and Mullins referred to a possible relationship between acute disseminated lupus erythematosus and periarteritis nodosa.

It would therefore seem that allergy plays a very considerable part in the aetiology of periarteritis nodosa, and, further, that a hypersensitive "soil" may be an essential factor in the development of the disease. In this connexion it is of interest to record that the son of Case 1 has been found to be suffering from Besnier's prurigo-eczema-asthma syndrome. Hypersensitivity to drugs of the sulphonamide series may be implicated in certain instances, and the apparently increasing incidence of the disease may be attributable to this fact. Sulphonamide drugs had been administered to Case 1 on several occasions. On the other hand, all inquiries regarding this aspect in Case 2 have been entirely negative. There can be little doubt that the disease existed before the sulphonamide era, and in some instances hypersensitivity to infective agents may be responsible.

Diagnosis

The possibility of periarteritis nodosa should be borne in mind in a case presenting multiple symptoms referable

to several systems. In Case 1 the diagnosis initially seemed to be that of pyrexia of uncertain origin, with emphasis on the possibility of enteric fever and abdominal tuberculosis. With the appearance of cutaneous nodules, periarteritis nodosa, carcinomatosis, and trichiniasis became possibilities; less probable causes in this case being bacterial endocarditis with multiple emboli, and Weber-Christian syndrome (Weber, 1925; Christian, 1928). The combination of myositis, abdominal pain, loss of weight, tachycardia, and fever, associated with cutaneous nodules, suggested periarteritis nodosa, and this was confirmed by histological examination of a nodule.

The triad of myositis, abdominal pain, and loss of weight has been referred to by Meyer and by Middleton and McCarter (1935). In a review by Bruce Logue and Mullins (1946) tachycardia and fever occurred in 87%, abdominal pain in 56%, myositis in 44%, loss of weight in 44%, and cutaneous nodules in 23% of cases.

It is regrettable that no characteristic lesions are observed on ophthalmoscopic examination, but emphasis should be placed on histological examination of cutaneous nodules in suspected cases, or in their absence success may attend muscle biopsy.

Treatment

From a review of the literature no treatment appears to have been of any value. Leishman (1937) confirms this view. Assessment of any particular treatment is difficult because of the infrequency with which the disease is diagnosed during life. Secondly, chronic forms characterized by exacerbations and remissions occur (Arkin, 1930; Macaigue and Nicaud, 1932). Lastly, Boyd (1944) emphasizes the conception of healed periarteritis nodosa with multiple chronic ischaemic lesions.

Penicillin.—As long-continued pyrexia suggested infection in Case 1, penicillin was tried, a total dosage of 4 mega units being given intramuscularly from Dec. 4 to 10. Penicillin in smaller dosage had been administered to Case 2 before admission to the Western Infirmary, Glasgow. No improvement occurred in either case during or immediately subsequent to penicillin therapy. Despite this it is possible that beneficial effects might ensue in cases in which a penicillin-sensitive micro-organism is acting as antigen. On the other hand, according to Suchecki (1946), allergic reaction to penicillin occurs in some 0.5% of cases. In such instances penicillin therapy may indeed be contraindicated.

Anti-histamine Preparations

The drugs used were β -dimethylaminoethyl benzhydryl ether hydrochloride ("benadryl") and histamine azoprotein ("lertigon"). These were employed on the basis of the histamine concept of allergy. Benadryl has histamine antagonizing properties (Loew, Kaiser, and Moore, 1945). It is thought to act by competing with histamine for a given site of action, and thus prevents the effect of histamine combination at this site. On the other hand, lertigon is said to produce antibodies which neutralize histamine before it can enter into combination at the site of action. Benadryl and lertigon are thus synergistic in action, and it would appear rational to use them concurrently.

In Case 1 benadryl was administered initially in doses of 50 mg., four times daily, and its administration coincided with a tendency of the temperature and pulse rate to return to average levels. It would appear, however, that benadryl has not been effective in preventing the retinal and alimentary tract exacerbations (March, 1947). No toxic effects have been observed; but it was noticed that a steady fall in the patient's weight ceased when the dose of benadryl was reduced. No explanation has been found for this

side-effect of benadryl, if indeed the drug was responsible for the loss of weight.

Lertigon therapy was started in May, 1947, being administered subcutaneously in increasing doses every fourth day, up to a maximum single dose of 1 ml. Subsequently the dose has been reduced to 1 ml. weekly. No toxic effects have been observed.

Since beginning this combined therapy no exacerbations of the disease process have occurred. The patient states that he feels well, his weight is stationary, and the erythrocyte sedimentation rate is within average limits. There is some evidence, however, that hypertension may be developing, possibly secondary to ischaemic renal lesions. Whilst no conclusions can be drawn from a single case, it is felt that therapy along similar lines may hold out promise for the future treatment of periarteritis nodosa, and perhaps of other conditions.

Summary

Two cases of periarteritis nodosa are reported. One case was diagnosed during life, and 16 months after admission the patient is in good health. The aetiology of the disease is reviewed. It would appear that periarteritis nodosa is an expression of an allergic state to either micro-organisms or drugs—e.g., sulphonamides.

Observations are made regarding diagnosis. Emphasis is placed on clinical diagnosis, and the importance of histological examination of cutaneous nodules or muscle tissue in any doubtful case is stressed.

The results of treatment with penicillin, benadryl and lertigon are reported. Encouraging results have followed combined benadryl and lertigon therapy in one case.

I wish to express my thanks to Dr. D. K. Adams for encouragement and advice in writing this paper, and for his permission to publish the cases. My thanks are also due to Prof. D. F. Cappell and Prof. W. J. B. Riddell for their helpful criticisms, and to various colleagues whose assistance I have acknowledged in some instances by name.

Mr. James Griffiths, Minister of National Insurance, points out in a message he has sent to all members of the staff of his department that 700 of the 1,000 local national-insurance offices ultimately needed are already open and the necessary wide and intimate contacts with the public have already begun. He adds: "We must never forget that for the most part we shall be dealing with people who are ill or in trouble or are perplexed by some point or other. They will need not only the benefits due to them but in many cases help and advice also. There have already been many difficulties and there will be more. We are compelled to go forward in face of shortages of premises, of staff, and of equipment of every kind. Success must depend not only on the initiative and leadership of those in key positions but also on an alert and willing response from all. I have found everywhere the keenest enthusiasm and a high sense of the great social mission with which the Ministry is charged. This is going to be a soldier's battle for us and I am confident that every member of the staff, from the highest to the lowest, will do his best and not spare himself in the critical months that lie ahead of us."

Medical Memoranda

Otitis Media in Infancy

The following brief statistical survey indicates that otitis media in infancy remains a major clinical problem in a large children's hospital. It shows the results of treatment with penicillin and sulphonamides and of the surgical procedures of myringotomy and posterior drainage of the mastoid antrum.

Of 7,805 admissions to the wards of Alder Hey Children's Hospital, Liverpool, during the year 1946, 1,107 were infants under the age of 12 months. This number includes medical, surgical, and orthopaedic conditions, as well as primary aural diseases and cases of feeding error. Of these 1,107 infants 240 had an aural infection on admission; in the remaining 867 the ears appeared normal when first seen but 191 later developed otitis media or mastoiditis—a total of 431 (39%) infants with ear disease. Of these, 268 recovered and 163 (38%) died. The following surgical procedures were carried out:

Bilateral myringotomies in 227 cases (109 died)
 Unilateral " 18 " (2 " "
 Posterior drainage also " 64 " (45 ")

TABLE I—Relationship of Otitis Media to Parenteral Infections

	Recovered	Died	Total
1. Respiratory—			
Bronchitis or pneumonia with otitis media or mastoiditis	60	13 (22%)	107
Bronchitis or pneumonia without complicating aural disease	6	22 (22%)	216
2. Alimentary—			
Gastro-enteritis with otitis media or mastoiditis	112	75 (67%)	153
Gastro-enteritis without complicating aural disease	11	45 (81%)	159

* Of these 26 died within 24 hours of admission.

TABLE II—Results of Treatment of 431 Infants with Aural Disease

Treatment	Recovered	Died	Total
Penicillin alone	32	14 (30%)	46
Chemotherapy alone	105	31 (29%)	136
Both penicillin and chemotherapy (extremely ill cases)	192	164 (85%)	256
No specific treatment (includes both mild infections and those dying within a few hours of admission before treatment had begun)	29	14 (31%)	43
Total	268	163 (61%)	431

These figures are striking in that they reveal the high incidence of otitis media in infants in hospital. Barrier-nursing technique was observed in all cases whether admitted to general wards or individual cubicles. The environment seemed to have no significant bearing on the subsequent development of the disease.

Prolonged clinical observation bears out the extreme difficulty of assessing whether otitis media is primary or secondary in cases in which respiratory or alimentary infections are also present.

CONCLUSIONS

On the question of treatment it is very difficult to draw specific conclusions, one can only generalize. There is no great difference between the results of those treated with myringotomy alone and those having posterior drainage; the mortality rate in both groups is high. Posterior drainage is performed by some surgeons only when symptoms persist after repeated myringotomies, whereas others consider that posterior drainage is indicated if there is no improvement after one adequate paracentesis.

Penicillin appears to have only a small place in the treatment of otitis media in young infants—possibly because of lack of sensitivity of the infecting organism. The mortality rate is high in spite of treatment with sulphonamides, penicillin, and intravenous fluids to combat dehydration.

Thanks are due to Dr. W. E. Crosbie, medical superintendent, Alder Hey Children's Hospital, for permission to publish these figures, to Professor Norman B. Capon for his kind interest and advice, and to Dr. Margaret Rogerson for assistance.

 Deputy Medical Superintendent,
 Alder Hey Children's Hospital.

Reviews

GYNAECOLOGY REFRESHER

Obstetrics and Gynaecology. A Revision Course for Practitioners. By C. Scott Russell, M.B., F.R.C.S.Ed., M.R.C.O.G. With foreword by J. Chassar Moir, D.M., F.R.C.S.Ed., F.R.C.O.G. Oxford Medical Publications. (Pp. 214; 21 figures. 12s. 6d.) London: Geoffrey Cumberlege (Oxford University Press). 1947.

The author has written this book for medical men returning to civilian practice who want to revise obstetrics and gynaecology and for any others who wish to refresh their memory. It is a small volume, just large enough to slip into the pocket, yet it contains an extraordinary amount of practical and useful information covering the whole of obstetrics and as much gynaecology as the practitioner is likely to need in his everyday work. On almost every page there is evidence that the author, far from repeating merely secondhand opinions, is himself a close observer, able to transform his observations into practical conclusions and to convey these conclusions to the reader in clear and convincing form. We like the advice given in discussing the management of the second stage of labour: "In all cases the foetal heart should be listened to carefully during the half hour following the rupture of the membranes, as one of the signs of cord prolapse may be a failure of the heart rate to pick up between pains." We like too the use of the radio in uterine inertia to keep the patient cheerful, but are less sure about the value of applying the forceps in constriction ring.

Though the author has done his work well, it must be said that obstetrics is not an easy subject to master. It requires much reading and long experience. It cannot therefore be expected that a small book such as this will equip the practitioner for the practice of midwifery, and it will probably be best read in conjunction with and as a supplement to some longer textbook. If this is done it will well repay careful study. As Prof. Chassar Moir says in the foreword, "It will stimulate an interest and will encourage the reader to a fuller study of the subject."

F. J. BROWNE.

HESS IN BRITAIN

The Case of Rudolf Hess. A Problem in Diagnosis and Forensic Medicine. Edited by J. R. Rees, M.D., F.R.C.P. (Pp. 224. 12s. 6d.) London: William Heinemann. 1947.

The main problem presented by this book is whether or not Hess was suffering from a paranoid schizophrenia during his stay in England. The authors conclude, though with reserve, that he probably was. The case is obscured by evidence of a psychopathic personality and by the repeated occurrence and remission—most dramatically during his trial—of a hysterical amnesia. In this account the authors consider these side-issues to a disproportionate extent and do not adequately discuss the more fundamental question of diagnosis.

Hess flew to England on May 10, 1941, apparently quite impulsively, on the conviction that he personally had only to say a few words to the King for peace to be declared. As soon as May 22 he was saying that he was surrounded by Secret Service agents who would drive him to commit suicide or poison his food. The systematized paranoia so begun persisted ever since. Early on he believed that doors were opened and shut and motor-cycles kept running to prey on his nerves. He would not eat unless others sampled the food. From time to time he would say he could not concentrate, that his mind went blank. An interview with Lord Simon revealed that the reason given for his flight had no basis in fact. Thereafter he was worse. All the people around him were under an evil influence, hypnotic or chemical, unconscious agents in a conspiracy to do him harm. In the early hours of July 15 he dashed suddenly about a corridor, "his face one of extreme despair, his eyes staring and his hands flung over a second-floor banister, breaking it." After that shifts of nurses watched him day and night but he was still recorded as "not medico-legally insane."

In July, 1941, he came under the care of a psychiatrist with mental-hospital experience and was regarded as a characteristic mental-hospital inmate. He would lie with his fingers in his ears, smiling to himself, and when questioned would reply, "I am thinking." He hoarded odd bits of paper about the room and under the couch. In subsequent years, apart from the coming and going of amnesic states, he changed little. Auditory hallucinations were observed. He made a second attempt at suicide by plunging a bread-knife into his breast. In February, 1945, he handed in a medley of names of august personages and personal attendants under the hypnotic influence of the Jews. In October, 1945, he was transferred to Nuremberg gaol. He took with him a statement meant to be the basis of his case, a farrago of delusional material without relevance to legal or political issues. In it he says that the eyes of the people around him had a glassy look and changed from time to time, the result of an abnormal mental condition caused by a secret chemical; his food was contaminated by secretion from camels' and pigs' glands; his dictionary decayed when he touched it; his apples were injected with "hot poison." In Nuremberg gaol primary delusions were still appearing: "I will look at a piece of bread, and suddenly I feel sure it has been poisoned." Schizophrenic ambivalence was shown: asked for his signature, he would write it and immediately scratch it out, this performance being repeated several times. Nevertheless the medical commissions found him not insane but fit to plead, and the Russian physicians state a definite opinion that he was simulating and that his past paranoid illness was psychogenic. He was, however, then in an amnesic state, and the delusions had for the time receded, though they were to recur.

Hess's illness, therefore, is a chronic paranoid condition, progressive and without tendency to remission. It thus bears no resemblance to a purely psychogenic state. Hardly one of the most characteristic schizophrenic symptoms is lacking: primary delusions, systematization of delusions of a highly bizarre type, hallucinations in a clear state of consciousness, thought disorder and incoherence, affective impoverishment, and ambivalence and other gross disturbances of volition.

This analysis, when contrasted with that provided in the book, throws into relief the differences between two schools of psychiatry. Considered in the terms of a psychotherapeutic discipline, Hess's case was one of great difficulty and obscurity. Considered in the terms of a classical psychiatry, it was unambiguously schizophrenic from the beginning. The reason for the authors' doubts and hesitations is to be found in the inadequate theory by which, in common with others of their school, they were bound. They state (p. 212) that they attach relatively small importance to "diagnostic labels." In this they throw overboard a whole field of psychiatric knowledge. The making of a diagnosis of schizophrenia is not a bagatelle, but is fraught with consequences of a prognostic, therapeutic, and medico-legal kind. It was a fateful circumstance for Hess that a diagnosis of schizophrenia was reached only after several years, and after his trial was over.

ELIOT SLATER.

BASAL GANGLIA

Diseases of the Basal Ganglia and Subthalamic Nuclei. By D. Denny-Brown, M.D., Dr.Phil., F.R.C.P. Edited by Henry A. Christian, M.D., Sc.D., F.A.C.P., F.R.C.P.(Can.). (Pp. 45. 12s. 6d.) New York and London: Geoffrey Cumberlege (Oxford University Press).

This book, published as a separate monograph, is a chapter written by Prof. Denny-Brown for the *Oxford Loose-leaf Medicine*. In the earlier and more important part he has reviewed the literature on the diseases of the basal ganglia with reasoned criticism and much selection against the background of the anatomy and physiological activity of the basal grey matter.

Prof. Denny-Brown strives to show the relation of the extra-pyramidal system to that of the pyramidal, cerebellar, and sensory systems in the control of voluntary movement, and then to demonstrate in the various syndromes which he has discussed the deprivation of function caused by the lesion, and the significance of the residue. This is an admirable work of reference and a clinical exposition in the best tradition.

DENIS WILLIAMS.

TRAINING AFRICAN NURSES

African Medical Handbook. An outline of medicine and hospital practice for African nurses, orderlies and medical assistants. By Michael Gelfand, M.B., M.R.C.P. (Pp. 206, 22 figures. 15s.) Christown: The African Bookman. P.O. Box 3115.

One of the greatest medical problems of the day is how to provide medical treatment for the vast undeveloped areas of Africa. There are far too few European doctors and in many cases they cannot understand the languages of the peoples with whom they have to deal. African doctors also are lacking. Apart from inadequate facilities for medical teaching there are as yet far too few people with the requisite secondary education to enable them to benefit from Western medical training. In this dilemma an answer has been found in the provision of African dressers, nursing orderlies, and medical assistants, who in many countries have already been placed in charge of important dispensaries. Textbooks are obviously required for the teaching of the African subordinate medical and nursing staff, but although a beginning has been made in Uganda and the Belgian Congo the supply is insufficient. The writing of such books is by no means easy: they must be written clearly and simply, for many Africans have only small knowledge of English; they must be absolutely accurate for the African still firmly believes in the infallibility of the printed word; and finally they must tell exactly what the African must and must not do in all the emergencies with which he may be called upon to deal.

Dr. Gelfand comes out of the tropics with burnt colours. On the second count there is less certainty for there are many minor inaccuracies. No one can diagnose sickling of red cells by placing a drop of blood on a slide and covering it with a cover-glass however long he leaves it in 1946 when he rings the cover-glass with vaseline. Red blood cells will not be found in the urine in blackwater fever (p. 195). Blackwater fever occurs more frequently in children than in adults in West Africa (p. 77). Many of the names of diseases used are no longer current—for example: "M. fever," "catarrhal jaundice," and "climatic bubo," while the current use of "M. and B. drug" as a synonym for chlorpromazine is deprecated. Infective hepatitis is the name of a specific disease (p. 195). These, however, are minor blemishes which can be removed when a second edition is called for.

The author is at his best in describing treatment in detail from his extensive knowledge of work in a large African hospital, and the instructions in most cases are clear and concise. Some readers, however, would look askance at treating early cases of Gambian sleeping sickness with trypanamide alone. There is no mention of the use of penicillin in the treatment of tropical ulcer, and curiously enough no mention at all of such a common disease as influenza or influenzal pneumonia, though he refers to such rare complaints as mumps encephalitis and to asbestosis. In many parts of Africa carbon tetrachloride has been given up in favour of the much less toxic carbon tetrachloroethylene. A special word of praise must be given to the numerous line drawings by Mr. H. H. D. Simmonds; these will do much to lighten the African's task in grasping the main facts of the cause and cure of common diseases.

G. M. FINDLAY.

The Collected Papers of the Mayo Clinic and the Mayo Foundation, Vol. XXXVIII, 1946, edited by Dr. Richard M. Hewitt and others (W. B. Saunders, 63s.), fall into certain broad groups. There are the hardy annuals such as peptic ulcer, cancer, and peripheral vascular disease, on which there is always something, if nothing fresh, to say. Then there are the Mayo Clinic contributions to recently described or rediscovered syndromes, such as Meig's syndrome, cystic fibrosis of the pancreas, or diffuse amyloidosis with macroglossia, in which a few i's are dotted and a few t's crossed. More useful are the reviews of series of cases—e.g., a study of 31 cases of primary carcinoma of the liver or the review of 83 proved cases of multiple myeloma. Finally there are the papers on subjects which workers at the Mayo Clinic have made their own, such as the group of papers on streptomycin or Allen's report on treatment with dicoumarol. Though there is nothing exciting in these 900 pages, they are nevertheless a fair summary of recent advances in routine hospital work. Few of us would choose this as preferred reading, but few of us, again, would not find much of interest and profit if this were the only book in the house on a wet week-end.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received.]

Disputed Paternity Proceedings. By S. B. Schachin. 2nd ed. (Pp. 614. No price.) New York: Banks and Company. 1947.

A general account of the medical and legal aspects.

Clinical Ophthalmology. By H. M. Traquair, M.D., F.R.C.S. Ed. (Pp. 264. 25s.) London: Henry Kimpton. 1948.

An introduction to ophthalmology for general practitioners and students.

The Social Sciences. A case for their greater use (Pp. 26. 1s. 6d.) Prepared by the Social Science Committee of the Association of Scientific Workers, London.

A pamphlet advocating the greater use of the social sciences.

Transactions of the Medical Society of London. Vol. 64. Edited by W. E. Tanner, M.S., F.R.C.S. (Pp. 254. No price.) London: Harrison and Sons.

Papers on a wide variety of topics presented during 1944-6.

Practical Food Inspection. By C. R. A. Martin. Vol. 2. 3rd ed. (Pp. 284. 18s.) London: H. K. Lewis. 1946.

The inspection of food other than meat from animals killed in slaughterhouses.

Oxford Essays on Psychology. By William James D.M., D.Sc., F.R.C.P. (Pp. 148. 10s. 6d.) London: William Heinemann. 1947.

Lectures on general psychology delivered at Oxford.

Modern Psychiatry in Practice. By W. A. G. Webster, B.Sc., M.D., M.R.C.P. 2nd ed. (Pp. 275. 10s. 6d.) London: J. and A. Churchill. 1945.

A general introduction to the practice of psychiatry for student and practitioner.

The Universe in the Making. By J. L. R. M. Dinnage, F.R.C.S. (Pp. 174. 7s. 6d.) London: Clarendon. 1945.

A medical man's personal account of the universe.

Basic Facts of Health Education. By W. P. Kennedy, Ph.D., L.R.C.P., F.R.S. Ed. 2nd ed. (Pp. 197. 7s. 6d.) London: The Pharmaceutical Press. 1947.

A collection of short articles for pharmacists.

Voluntary Social Services since 1910. By Henry A. Moss et al. (Pp. 255. 21s.) London: Kegan Paul, Trench, Trubner. 1948.

A review of the social services in Britain.

Harmony of Nature. By L. Richmond Wheeler. (Pp. 200. 6s. 6d.) London: Edward Arnold. 1947.

The author, a biologist, elaborates his theory of "co-operation or co-existence" in nature.

The Psychology of Diet and Nutrition. By L. S. Sellings, M.D., and M. A. S. Ferraro, M.S. (Pp. 192. 8s. 6d.) London: John Lane The Bodley Head. 1947.

A simple account by a dietitian and a psychiatrist intended for dietitians and housewives.

Tuberculosis in the Commonwealth, 1947. (Pp. 328. 15s.) London: Pendragon. 1947.

The transactions of the Commonwealth and Empire Tuberculosis Conference convened by the N.A.P.T. in 1947.

Psychiatry: a Short Treatise. By W. A. O'Connor, L.M.S.S.A., D.P.M. (Pp. 380. 35s.) Bristol: John Wright. 1948.

A general introduction to psychiatry.

An Outline of the Development of Science. By Mansel Davies. (Pp. 214. 3s. 6d.) London: Watts (Thinker's Library). 1947.

A short history, with illustrations.

Clinical Endocrinology and Constitutional Medicine. By A. P. Cawadiaz, O.B.E., M.D., F.R.C.P. (Pp. 362. 42s.) London: Frederick Muller. 1947.

The author stresses the clinical aspects of endocrinology and includes a number of illustrations.

Nova et Vetera

THE AMERICAN SYDENHAM

During the present century general historians in America have begun to turn their attention towards Benjamin Rush, of Philadelphia, and have dealt with his contributions to social reform and to education. Although Rush was never a major political figure he belonged to a group of versatile individuals who helped to bring about the independence of the United States. One of the five medical men who signed the Declaration of Independence, he was also a member of the Constitutional Congress and was for many years Treasurer of the U.S. Mint. Nevertheless, as a national figure Rush has been overshadowed by such men as John Adams, Thomas Jefferson, Benjamin Thompson, and that other embodiment of eighteenth-century versatility, Benjamin Franklin. Rush, however, has never been neglected by the members of his own profession, and his position as the leading medical man of his time has not been challenged. He has been hailed as the American Sydenham and as the Father of American Psychiatry. Papers read at a special meeting of the College of Physicians of Philadelphia, held on Nov. 6, 1946, to commemorate the 200th anniversary of the birth of Rush, who was one of the founders of the College, have now been printed,¹ and these provide a valuable supplement to the full-length life by Dr. Nathan Goodman published in 1934.

The first paper in this symposium is by Dr. R. H. Shryock, who refers to the wide divergence of views concerning Rush held both by his contemporaries and by present-day writers. These range from John Coakley Lettsom's claim that Rush combined judgment and sagacity "in almost unprecedented degree" to Elisha Bartlett's acid observation that there was more "utter nonsense and unqualified absurdity" in Rush's works than in the whole compass of medical literature. According to some critics Rush's voluminous *Medical Inquiries and Observations* contain nothing of value and only serve to show how easy it is for a facile writer to build up an unmerited reputation; others regard his writings as a mine of valuable clinical records and as containing many forecasts of modern views.

Rush was of English Quaker descent, and was born in Byberry Township, Philadelphia County, in 1745. After taking his B.A. degree at Princeton in 1760 he was apprenticed for six years to Dr. John Redman, of Philadelphia. He attended the first course of lectures on anatomy given in 1762 by Dr. William Shippen the younger, a pupil of the Hunters and the friend of John Fothergill. Like so many of his compatriots Rush came to Edinburgh, where he took his M.D. in 1768, and he then studied in London and Paris. On his return to America in 1769 he was elected professor of chemistry in the College of Philadelphia. His appointment completed the medical faculty of the first medical school established in what is now the United States. In 1789 he succeeded John Morgan as professor of the theory and practice of medicine in the College of Philadelphia, and when in 1791 the University of Pennsylvania was founded Rush was appointed professor of the institutes of medicine and of clinical medicine. In 1796 he received the additional appointment of professor of the practice of physic, and he also acted as physician to the Pennsylvania Hospital. During the revolutionary war he was physician-general to the military hospitals of the Middle Department of the United States Army. He died in 1813.

Dr. Shryock deals at length with Rush's theory of pathology. The prevailing medical teaching of his day was that of Cullen, according to which diseases were minutely classified and every disease was supposed to possess an appropriate specific treatment. Rush rejected the nosological arrangement of diseases and expounded a modified form of brunonianism. He claimed that all fevers resulted from (1) a predisposing debility, (2) a remote cause, which was the immediate inciting cause, operating upon a debilitated body, to produce (3) a convulsive excitement or "crisis" action in the walls of the blood vessels. Subsequently

he declared this "convulsive action" to be the underlying feature of all apparently distinct forms of illness. Dr. Shryock points out that in certain respects Rush's views no longer seem so strange to medical thinking as they did to his contemporaries and immediate successors. "Predisposing debility" was analogous to the modern idea of lowered resistance. Stimulus (the immediate exciting cause) was conceived broadly enough to include anything which would be listed to-day as an external aetiological factor.

Rush was certainly the ablest American clinician of his time. He described cholera infantum (1773) and gave one of the earliest accounts of dengue (1780). He wrote a valuable pamphlet on the hygiene of troops (1797), and his accounts of the North American Indians (1774 and 1778) and of the German inhabitants of Pennsylvania are among the earliest American contributions to anthropology. The original bent of his mind is shown in his inquiries into the effects of alcohol on the mind, into focal sepsis, and into the use of arsenic in cancer. His *Medical Inquiries and Observations upon the Diseases of the Mind* (1812) is the earliest systematic American treatise on the subject. One of Rush's most famous writings is his account of the Philadelphia epidemic of yellow fever in 1793. Rush took a leading part in fighting this epidemic, and incurred the hatred of his fellow citizens by proclaiming that the fever was the result of filth in the streets and not an importation. His treatment consisted mainly in venesection and purgation, low temperature in the sick-room, and the application of cold water both within and without. He gave purgatives in enormous doses—a powder of 10 gr. of calomel and 15 gr. of jalap administered not once but repeatedly. As a blood-letter Rush was a veritable Sangrado. He did not hesitate to remove a quart at a time and to repeat this procedure two or three times within forty-eight or seventy-two hours. "Bleeding," he wrote, "should be repeated while the symptoms which first indicated it continue, should it be until four-fifths of the blood contained in the body are drawn away." Rush claimed that many more patients with yellow fever recovered under his treatment than under the older use of wine, blisters, and bark. Dr. Philip Syng Physick ascribed his own recovery from yellow fever to his treatment by Rush with the removal of 76 oz. of blood by 22 bleedings in ten days. Rush's claims were hotly contested by William Cobbett and by many of his medical colleagues.

In the second paper in this symposium Prof. O. H. Perry Pepper deals with "Benjamin Rush's theories on blood-letting after one hundred and fifty years." Rush found indications for bleeding not only in the pulse but also in the appearance of the blood in the bleeding-bowl. He was especially impressed by blood covered with a buffy coat. This blood was termed "sizy," and the more sizy the blood the more clear the indication for bleeding, according to Rush. Prof. Pepper points out that Rush was partly right in using the thickness of the size as an indication of the presence of an inflammatory process, and he gives an interesting account of the growth of knowledge concerning the significance of the sedimentation rate. What Rush did not know was that anaemia of itself increased the sedimentation rate and, of course, the siziness of the blood. Each blood-letting therefore paved the way for another, for each removal of blood made the patient more and more anaemic.

Appended to these two lectures is a list of "Benjamin Rush's apprenticed students," taken by Mr. James E. Gibson from a notebook in the Rush Manuscript Collection in the Ridgway Library, Philadelphia. This list contains the names of 135 apprentices who lived with the Rush family and in near-by lodgings between 1770 and 1812. Rush selected his apprentices with care; the majority were the sons of personal friends or were recommended by his old students. In 1776 each pupil paid a fee of 100 guineas.

Wellcome Historical Medical Library.

W. J. BISHOP.

The Royal College of Nursing will hold a conference from May 31 to June 2 in order to discuss design, equipment, and administration. Tickets in the first place will be allocated through the branches and sections of the College and through affiliated associations. Any remaining tickets, for which the fee is one guinea, may be obtained on application to the Conference Secretary, Royal College of Nursing, Henrietta Place, Cavendish Square, London, W.1.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY MAY 1 1948

YES AND NO

The result of the fourth plebiscite to be held by the British Medical Association will be known soon after this issue of the *Journal* is published. If the majority of consultants and specialists, general practitioners, and those working whole-time in voluntary hospitals vote against accepting service, and if this majority includes approximately 13,000 general practitioners, the B.M.A. will continue to advise the medical profession not to enter the National Health Service on July 5. The corollary of this is that if the majority as stated is not secured the B.M.A. will not offer this advice. Should the majority be in favour of accepting service in view of the changed situation resulting from Mr. Bevan's concessions, the Representative Body may consider it wise to urge the minority to enter the new Service so that the majority may have a fair chance of giving the public at least some of the benefits that have been so extravagantly promised it. The facilities for a comprehensive medical service for all will not be available on July 5, and a disappointed public will look for a scapegoat. There will probably be some men who on grounds of conscience will not enter a State medical service. They demand the respect always accorded in this country to the objector who is conscientious. If as a profession we behave with dignity and show tolerance to those who differ we shall avoid the bitterness attending the introduction of the National Health Insurance Act of 1911. If as medical men and women we fall out among ourselves we shall lose the strength of unity which was so dramatically demonstrated when Mr. Bevan's intransigence provoked an overwhelming vote of no confidence in the National Health Service Act in the form in which it was before the profession in January of this year. Mr. Bevan and the Government were compelled by the plebiscite of February to introduce an Amending Act which in December last Mr. Bevan refused even to contemplate. We believe that this is the first time any section of the community has been successful in persuading the Government to modify an Act already on the Statute Book, an Act, moreover, endorsed by a Parliamentary majority in the ill-starred and unprecedented debate in the House of Commons on Feb. 9.

The plebiscite of February taught us one thing, and that is that when medical men and women are convinced that their professional and intellectual freedom is threatened they can unite to good effect. If the present plebiscite does not produce a result similar to that held in February it may

be argued that conviction is now lacking. That Mr. Bevan has made concessions was acknowledged by Dr. H. Guy Dain, the Chairman of Council, in a letter published in last week's *Journal*. The B.M.A. Council considered that these concessions had not sufficiently safeguarded the freedoms of the profession. Public opinion, a powerful force not to be lightly disregarded, inclines to the opposite point of view. This opposite point of view is shared by many responsible medical men whose opinions command respect. For example, at a meeting held by consultants in B.M.A. House last week, an account of which appears elsewhere, Sir Reginald Watson-Jones, who had openly declared his opposition to the Act before the Minister had made his concessions, advised those present to accept service in view of the changed situation.

It is possible that the present plebiscite will show an almost equal division of opinion on whether or not to enter the Service. If this happens the medical profession will be in a dilemma. In that event we shall be faced with the paradox that when Mr. Bevan tried by opposition to split the profession he failed, and that now by making concessions in a conciliatory manner he has succeeded in dividing us. If approximately half those who vote are prepared to enter the Service, then Mr. Bevan may well believe that he has enough medical men with which to operate it on July 5. But neither Mr. Bevan, nor the medical profession, nor the British public will be able to look upon this situation with anything but dismay. At all costs we must strive to preserve our unity and agree to differ, if differ we must, in a spirit of tolerance. The forces that bind medical men together are much stronger than those that tend to separate them. We must, too, remind ourselves that the B.M.A. has declared its "whole-hearted desire" for a comprehensive medical service available to everyone in Britain. The Representative Body voted in favour of "the 100" issue. These two things added together mean a national medical service. What matters to the medical man working in this service is his freedom to apply the art and science of Medicine according to his training and his conscience, and his freedom to express his opinion by voice and pen on all aspects of professional life, including the administration of the service in which he works. We have always held that these freedoms and free choice of doctor could not be maintained in a full-salaried State medical service. The promised Amending Act would seem to be a sufficient safeguard against the introduction of a full-salaried service under the National Health Service Acts of 1946 and 1947. Mr. Bevan has agreed to include in the terms of contract his assurance that freedom of opinion on all aspects of professional life will be safeguarded. Those who think these are not sufficient must determine "as reasonable people"—to quote Dr. Dain's words—what other safeguards are necessary and endeavour to obtain them. The Edinburgh Division of the B.M.A. on Sunday reminded us, too, of the need for "warning the public that the full range of service will not be available for many years to come." On this point the public has been misled by ill-informed publicists, and it will need repeated correction.

THE MEGALOBlastic ANAEMIAS

In no branch of medicine has factual knowledge accumulated more rapidly in recent years than on the subject of the anaemias. This has been accompanied by a reorientation of ideas, preoccupation with cytology having been replaced by an interest in metabolic, chemical, and nutritional factors underlying haemopoiesis. The initial stimulus was provided by Minot and Murphy's¹ demonstration that patients with Addisonian pernicious anaemia could be restored to health by the addition of liver to their diets. Peabody had already shown that in this disorder there was a proliferation of primitive erythroblasts in the bone-marrow and that this megaloblastic hyperplasia gave place to a normoblastic haemopoiesis when remission occurred. Sternal puncture has demonstrated that there is a group of anaemias to which this megaloblastic change in the bone-marrow is common.

Although the megaloblast has long provided haematologists with material for acrimonious argument, the appearance of megaloblastic hyperplasia is so typical that it can be recognized by the tyro. All agree on the appearances, but interpretation is still debated. Peabody suggested that an arrest of maturation was the underlying fault, and owing to the confusion caused by the varied meanings imputed to the term megaloblast it was for long believed that the cells of the bone-marrow in pernicious anaemia were erythroblasts of an immature type which existed in normal marrow in scanty numbers. It is now generally accepted that the megaloblast is a pathological erythroblast which is seen, with rare exceptions, only in the marrow of patients with the anaemias now under discussion. "Maturation arrest" cannot describe this change because such cells do not represent a stage in normal maturation. It is still uncertain whether the reversion to normoblastic erythropoiesis which accompanies remission entails a rapid maturation of megaloblasts to form megalocytes, or whether a megaloblast can be transformed into a normoblast of the same maturity. Confusion has been increased recently by claims to recognize cells intermediate between normoblasts and megaloblasts, and if their existence is accepted such transformation must be granted. Mallarmé² has called the megaloblast a normoblast suffering from a nutritional deficiency, and it may be that grades of deficiency exist.

The anaemias which share this characteristic bone-marrow change may be spoken of, as Davidson and Davis³ have suggested, as the megaloblastic anaemias. The main members of the group are Addisonian pernicious anaemia, pernicious anaemia of *Diphyllobothrium latum* infestation, pernicious anaemia of pregnancy, nutritional megalocytic anaemia, the megaloblastic anaemias of infancy and childhood, the megaloblastic anaemia accompanying steatorrhoea, and certain refractory megalocytic anaemias. It is rational to seek for these various disorders a common cause, and Castle's hypothesis seemed to provide this. However difficulties arose when it was found that different members of the group responded differently to treatment with liver preparations, which *ex hypothesi* should have

been fully effective in all. The preparations generally in use can be classed as refined extracts for injection, crude extracts for injection, and proteolysed liver for administration by mouth. Addisonian pernicious anaemia and that due to the broad tapeworm respond adequately to all of these. Pernicious anaemia differs from others of the group in its association with degeneration of nervous tissues, from which danger adequate dosage with liver protects the patient. Von Bonsdorff⁴ has suggested that pernicious tapeworm anaemia is due to the inhibition of the interaction of the intrinsic and extrinsic factors, which occurs only when the worm is sufficiently high in the intestine. In the other anaemias of this type response to refined liver extracts is absent or indifferent. Crude extracts are effective in some, while in others proteolysed liver is apparently the only useful preparation. In this group Davidson⁵ would place idiopathic refractory megaloblastic anaemia, which appears to be the condition described by Israels and Wilkinson as achrestic anaemia. Watson and Castle⁶ have been able to separate two varieties of nutritional megaloblastic anaemia, one responding to refined extracts and the other to crude extracts or yeast.

Matters had reached this degree of confusion and complexity when the discovery of folic acid was announced. The steps which led to the isolation and later to the synthesis of this substance are recounted in Dr. J. F. Wilkinson's papers, the second of which appears in this number of the *Journal*. He and others have shown that it is effective in all forms of megaloblastosis of the bone-marrow. How completely efficacious it may be is not yet agreed, because there is some evidence that satisfactory blood levels are not always maintained. In the steatorrhoeas, in which a mixed megaloblastic-normoblastic hyperplasia is common, he finds it effective in proportion to the degree of megaloblastosis. The problem has now become how to fit folic acid into the aetiological puzzle. Since all megaloblastic marrows become normoblastic under the influence of folic acid it seems likely that this substance is itself the essential missing factor. Refined liver extracts, effective in pernicious anaemia, are virtually devoid of folic acid, and Davidson⁵ has suggested that they act by liberating folic acid from the inert conjugated form in which it exists in the diet. The other megaloblastic anaemias he regards as due to a failure of supply of conjugated folic acid, since purified liver extract is ineffective in them. A paper by Prof. Davidson and others, describing the successful treatment with folic acid of three cases of pernicious anaemia of pregnancy which did not respond to injections of liver extract, appears elsewhere in this issue. Davidson's hypothesis does not fully explain the failure of folic acid treatment in some cases, nor the persistence of megalocytosis noted by Wilkinson, and he suggests a third factor may be present in proteolysed liver. Jacobson's⁷ observation that when folic acid is incubated with xanthopterase its haemopoietic activity is greatly increased indicates that the final solution may be more complicated. The most recent development in this field is the preparation of red pigments

(described as differing forms of the classical liver factor) from ox liver or proteolysed liver extracts which are reported to be effective in cases of pernicious anaemia and subacute combined degeneration in doses equivalent to some 20 µg. daily (possibly only 2.5 µg.).⁸

In pernicious anaemia folic acid has a greater theoretical than practical importance. Like others, Wilkinson has found that while controlling the anaemia it has no effect on the subacute combined degeneration of the cord. There are several reports which suggest that it increases the rapidity of onset of nervous symptoms. Ross, Belding, and Paegel⁹ consider that it may interfere with the metabolism of L-glutamic acid in the nervous system. Whatever the explanation, folic acid is a dangerous drug in pernicious anaemia, and the treatment of choice remains the injection of a potent liver extract. The place for folic acid is in the treatment of the other megaloblastic anaemias, which are often refractory to liver and in which changes in the nervous system do not occur.

THE NEW "B.P."

The publication, with effect from September next, of another *British Pharmacopoeia* is a noteworthy event. The new issue is the seventh of its series to appear under the auspices of the General Medical Council. The first was published in 1864 and the sixth in 1932. In normal times an interval of ten years is considered reasonable; the prolongation to the sixteen years separating the current and the forthcoming issues is due to war and post-war restrictions and frustrations. The issue of seven Addenda, six of them in wartime, has bridged the interval.

For the origin of the *Pharmacopoeia* it is necessary to go back to the reign of James I. The Royal College of Physicians of London issued the first *London Pharmacopoeia* in 1618; similar publications made their appearance in Edinburgh in 1699 and in Dublin in 1807, and all three continued through various editions down to the middle of the nineteenth century. The preparations contained in these three formularies, however, were not all uniform in strength, and in view of the confusions which arose occasion was taken in the Medical Act, 1858, which set up the General Medical Council, to ordain that the Council should publish under its direction "a Book containing a list of medicines and compounds, and the manner of preparing them, together with the true weights and measures by which they are to be prepared and mixed, and containing such other matter and things relating thereto as the General Medical Council shall think fit. . . ."

The new volume in its familiar red cover bearing the royal coat of arms and announcing itself as issued "by authority" (complete in every respect except the price, which has yet to be fixed by the Treasury) is larger than its predecessor, running to not far short of a thousand pages. The Pharmacopoeia Commission, which has carried through the long and arduous work of preparation, is a body consisting of ten members under the chairmanship of Prof. J. A. Gunn. Three of the members, including Prof. Gunn, were on the Commission which prepared the B.P. 1932, and the secretary, Dr. C. H. Hampshire, has

acted in that capacity for both issues. The task has been more laborious and exacting than has attended any previous issue, not excepting even the first, but the Commission has been assisted by many experts and counsellors, including a clinical committee of over twenty members, and eight other committees, some of them with several subcommittees. In a preface to the work the Pharmacopoeia Committee of the G.M.C., which has undertaken a general supervision, pays a high tribute to the Commission for its unsparing efforts to bring the publication up to the utmost possible level of completeness and accuracy.

The task of those engaged in compiling the *Pharmacopoeia* is continuous. The ink is hardly dry upon one publication before the work on the next is begun. The publication therefore cannot be, and never aspires to be, up to date. The vast amount of experiment in devising suitable formulae and assessing the value of new preparations forbids. The use of pharmaceutical products by the medical profession is subject to constant change. It is not only ephemeral preparations which have their day and cease to be, but drugs of high reputation and dependability have their periods of popularity and decline. New drugs make their appearance and are for a time acclaimed, and then experience shows that they do not quite fulfil expectations, and they recede into the background or are superseded by some preparation for which similar or greater claims are made. The enterprise of pharmacists, the experiments of laboratory workers, the eagerness of clinicians present a situation which, excellent as it is from the point of view of medical and pharmaceutical progress, offers obvious difficulties to the compilers of an official and authoritative publication who have to look, not to the immediate summer, but to five or ten years ahead. It may well happen that when a new *Pharmacopoeia* is published some preparation may be on the crest of its wave of usefulness and finds no mention at all, while another which has been virtually discarded may be the subject of the usual monographs.

The changes introduced into the new *Pharmacopoeia* are not so many as might be expected in view of the great progress which has taken place in the laboratories, but it must be remembered that the comparison is not with the 1932 issue but with that issue together with, and as modified by, the several Addenda subsequently brought out, the last of which appeared in 1945. Ever since a Colonial and Indian Addendum was issued at the beginning of this century an endeavour has been made to ensure that the *Pharmacopoeia* shall be suitable for the whole of the British Commonwealth; but only preparations in general use throughout the Empire are included, not the various substances which have had but a local favour.

It would be an interesting exercise to take all the seven *Pharmacopoeias* and trace through them the enlarging history of modern pharmacy. Probably the most impressive thing which would appear as the result of such a review would be the large accessions of knowledge which have widened the boundaries of pharmaceutical science and the ever-increasing precision of testing and analysis. One has only to reflect upon the extensions in therapeutics which have followed the introduction of hormones, vaccines, sera, vitamins. In this latest *Pharmacopoeia*, for example, it has been necessary to enter upon an entire reassessment of

the value of the drugs which have appeared as a result of the developments in chemotherapy. With all this the definitions have continually become more exact and the tests more stringent; new instruments and methods have been introduced; and the standards by which a substance can be regarded as having an adequate therapeutic value have been raised. Some years ago the *Fédération Internationale Pharmaceutique* laid down a formidable list of subjects which should have a place in the studies of the pharmaceutical student. It included analytical and biological, physiological and pathological chemistry, chemical and galenical pharmacy, pharmacognosy, micrography, toxicology, microbiology, crystallography, and disinfection, and that did not exhaust the list, which ran on into general hygiene and public health legislation. Then from time to time, as new and authoritative *Pharmacopoeias* come forward, the pharmacist must readjust his knowledge and his practice, finding as he does that the composition and character of the drugs and galenicals to which he has been accustomed are affected by the requirements of the new issue which replace those of the old.

A complaint has been made against recent issues of the *Pharmacopoeia*—a complaint which may possibly be levelled against the new one—that they have been constructed not so much for the retail pharmacist as for the large manufacturing laboratory, since it is only the latter which has the resources to perform all the tests set out in 200 recondite pages of the appendix in the new issue. But that, of course, does not apply to the large numbers of injections, solutions, pills, ointments, and other articles and preparations which are the subject of a very large proportion of the monographs, and which are not beyond the capacity of any retail pharmacy properly equipped. One of the striking features of this new compilation is the introduction of as many as fifty-seven new injections; the current *B.P.* includes only half a dozen. In the earlier edition also there was only one tablet preparation (glyceryl trinitrate); in the 1948 edition eighteen tablet preparations are included. Another change is the elimination of all the fresh infusions, the prescription of which has continued to decline, and in the new issue the principle of preparing infusions from concentrated preparations is fully recognized.

One rises from a preliminary study of the new compilation with an increased respect—perhaps an increased sympathy—for the pharmacist, the practitioner's loyal and painstaking ally, and a renewed appreciation of the skill and care which invariably go to the testing of drugs and the dispensing of prescriptions.

CONGENITAL MEGACOLON

Into the colon from above there comes a constant flow of intestinal contents. If there is not a corresponding evacuation from below, these contents accumulate and the bowel must enlarge to contain them. Accumulation of faeces in a grossly dilated bowel occurs in two quite distinct conditions. In the first, seen typically in neglected children or those with congenital malformations of the anus, the bowel over the struggle and loses the reflex to empty itself which should be produced by distension. The resulting mass of faeces may be enormous, and semi-fluid matter is forced past it to produce a distressing overflow diarrhoea.

The treatment, however, is simple and (given co-operation by those in charge of the child) satisfactory. In the second variety, on the contrary, the bowel is not indolent but makes violent efforts to evacuate its contents, efforts which are thwarted in some way or other which is far from being fully understood. The result is the picture described by Hirschsprung, with huge waves of visible peristalsis, vast discharges of gas and faeces at varying intervals, and a gross hypertrophy of the muscular wall of the bowel suggestively similar to that seen in the stomach behind a hypertrophic stenosis of the pylorus. This group can itself be subdivided into two distinct clinical types. In the first the stasis, though obstinate and distressing, is neither very dangerous nor intractable. It responds to a careful regimen, to excision of loops of bowel, to sympathectomy, and for some mysterious reason to the high spinal anaesthesia of which Prof. E. D. Telford and Mr. H. A. Haxton give such an encouraging account elsewhere in this issue. In the other type, however, all these methods of treatment fail. Affected children are pitiable creatures, grossly deformed by an enormous belly, passing from crisis to crisis of obstruction till a final one results in death. There must be some essential difference between the two categories, and a thorough comparison of x-ray and clinical observations should help to solve the problem. The work of Munro Cameron upon the absence of ganglia in low segments of the bowel in certain cases may provide a clue to the answer.

SEDIMENT IN THE STOMACH

An intricate study of the cytology of the gastric juice has recently been undertaken by Tomenius.¹ Early in his investigation he found that the sediment of resting juice obtained in the usual way was valueless for cytological study. Cells which reached the gastric juice, either by active diapedesis through the mucosa or by desquamation from the surface epithelium, were rapidly altered by the hydrochloric acid. Further damage was caused by the swallowed saliva or by regurgitation of the duodenal contents. As a result stained preparations consisted largely of amorphous material in which the remnants of cells could be identified with difficulty.

It was found that digestion of the cells by hydrochloric acid could be prevented by the administration of an isotonic solution of sodium bicarbonate by the continuous-drip process. To give this solution and to aspirate the saliva and prevent duodenal regurgitation Tomenius devised a stomach tube the lumen of which was divided into two. This tube reached only to the lower end of the oesophagus, and while saliva could be aspirated through one half isotonic sodium bicarbonate solution could be instilled through the other. In addition each division of the main tube contained a smaller tube. The first was a stomach tube for the recovery of the gastric contents, and the second extended to the duodenum so that continuous suction could be maintained and regurgitation prevented.

After preliminary investigation of the cells found in the saliva and the duodenal contents stained smears made from the material aspirated from the stomachs of normal individuals were studied. In these it was found that the sediment was scanty and cellular elements in it rare. Material was also obtained from 48 patients suffering from various complaints, including peptic ulceration, gastritis, carcinoma ventriculi, pernicious anaemia, and leukaemia. Normal smears were seen in cases of gastritis with achlorhydria,

¹ Tomenius, J. H., *Acta med. scand.*, Suppl., 1947, 189.

² Papanicolaou, G. N., *J. Amer. med. Ass.*, 1946, 131, 372.

gastric and duodenal ulcers without gastritis, and carcinoma of the cardia or pylorus. Abnormal sediment was obtained from patients with gastritis where acid secretion was present, and with advanced carcinomas of the body of the stomach even when associated with achlorhydria. In all these cases leucocytes were greatly increased, and in the smears obtained from the patients with cancer many red cells were present. No neoplastic cells were seen, which is in contrast to the work of Papanicolaou.²

The investigation carried out by Tomenius is a model for its thoroughness and shows up the errors which are likely to occur when gastric sediment is obtained by less careful methods. The lessons to be learnt from it are, however, few. Gastritis is now diagnosed more frequently abroad than in this country, but much more experience with this painstaking procedure is required before the finding of an abnormal gastric sediment can be accepted as evidence of the existence of the condition.

THE TOXICITY OF AGENIZED FLOUR

The latest work in this country on agene-treated flour was described in an annotation recently in these columns.¹ Keen interest in the subject has also been shown in the U.S.A., where Sir Edward Mellanby's observation that agenized flour caused hysteria in dogs supplied the necessary clue to workers who had already suspected that certain processed wheat products were a frequent cause of this abnormality. In two extensive investigations they have now fully confirmed Mellanby's conclusions, and have made progress in a study on the effect of agenized flour upon other animals and upon the human subject.

At Chicago a team headed by Silver² gave dogs a diet which was adequate in proteins, vitamins, and other nutrients, but which contained 70% of the heavily agenized white flour. Neurological disorders developed within a week, with symptoms which varied in each animal but which usually included ataxia, weakness, and typical epileptiform fits. When electroencephalographs were recorded daily a cerebral dysrhythmia indistinguishable from that of human epilepsy appeared within 48-72 hours after the start of the agenized diet. Monkeys developed asynergy, weakness, and tremors, sometimes accompanied by cerebral dysrhythmia. In cats ataxia was the most prominent feature. An abnormal accumulation of reddish pigment, presumably a porphyrin, appeared around the head, eyes, and nose of rats fed on agenized whole-wheat flour. As observed in this country, the toxic agent was found to be formed from the protein of the wheat, particularly from the gliadin fraction, while casein and lactalbumin also became toxic when treated with agene. Intravenous infusions of mixtures of synthetic amino-acids which had been so treated caused seizures in dogs, but the only individual acids with this effect were cysteine and cystine. In the previous annotation reference was made to the work of Moran³ in this country, who has also suggested that the toxic agent may be formed by the action of agene on amino-acids containing sulphur.

Elvehjem and his colleagues⁴ at Madison have shown that unbleached wheat, irrespective of variety, does not cause hysteria in dogs. When agenized flour was included as 84% of the diet the times which elapsed before the appearance of hysteria varied according to the concentration of agene which had been used. Thus when 1 cwt. of flour was treated with 1 g. of agene fits occurred after 13-39

days, whereas with 20 g. of agene fits were observed after only 2-5 days. On the other hand when flour treated with 1.2 g. of agene per cwt., which is about the level used commercially, was given to dogs as 30% of their food, which represents about the proportion of flour in the average human diet in the U.S.A., they remained free from hysteria over a period of 12 weeks. In studies of the blood of affected animals no biochemical abnormalities could be detected. In agreement with previous findings improving agents other than agene (NCl_3) did not cause flour to become toxic. Agenized flour was found to retain its toxic properties even after storage for several months. Investigation of the various fractions of agenized flour gave support to the view that the toxic agent is in the gliadin fraction, and not in the carbohydrate or lipid fractions. No ill effects were observed when agenized flour was fed to rats, guinea-pigs, or chicks; cats had convulsive seizures, while monkeys developed abnormal electro-encephalographic patterns without obvious hysteria. In preliminary experiments on 5 human subjects, aged 6-15 years, wheat products treated with 3-20 g. of agene per cwt. were given in amounts of 70-105 g. daily for 2-4 weeks, but no electroencephalographic abnormalities or symptoms resembling hysteria were observed.

Official recognition of the danger of agene as an improver for flour may be implied from the publication of a letter from F. G. Boudreau, Chairman of the Food and Nutrition Board of the U.S.A. National Research Council, to Dr. P. B. Dunbar, Commissioner of Food and Drugs. Recommendations are made that research on the nature of the toxic agent and its effects should be intensified, that plans for industrial plant using chlorine and chlorine dioxide, or other "improvers," should be prepared, while in the meantime the use of agene should be reduced to the minimum necessary for the type of flour which has to be treated. More rigid restrictions are not at present contemplated, since it is considered that a too drastic interference with familiar baking practices might well aggravate the present food crisis.

ERYTHROBLASTOSIS AND KERNICTERUS

The problem of erythroblastosis foetalis continues to become more complex. The theory of Rh sensitivity as first outlined by Levine⁵ has suffered so many modifications at the hands of the serologists that the facts of the matter have become dim owing to a mushroom growth of literature and a confused nomenclature. In the case of kernicterus, for example, it is now accepted that this encephalopathy results from incompatibility between an Rh-negative mother and an Rh-positive baby, with the consequent production of anti-Rh factors which pass from mother to foetus. Apart from the immediate risk to life, permanent damage to the central nervous system, causing spasticity, athetosis, or mental defect, is a frequent result of kernicterus, which is recognized morphologically by the staining of the basal nuclei of the brain with bile pigment, with a consequent degeneration of nerve cells.

A recent paper by Wiener and Brody⁶ seems to show that the matter is not quite so straightforward as most clinicians had hoped. Aware of apparent discrepancies, they have investigated kernicterus from both the laboratory and clinical standpoint, and in so doing have arrived at a new conception of the disease. They conclude that the clinical manifestations of erythroblastosis depend upon the quality as well as the quantity of abnormal bodies in the maternal

⁷ J. Pediatr., 1946, 29, 462.

serum; and that erythroblastosis foetalis comprises three rather than one major disease syndrome, depending on the type of antibody. These subdivisions are termed icterus gravis neonatorum, congenital haemolytic disease, and icterus praecox—the first two being of major importance. Icterus gravis neonatorum is thought to be due to bivalent antibodies (agglutinins) present in the maternal serum. Because of their size they are normally unable to pass through the placenta, but are “milked” into the foetal circulation by the uterine contractions at birth. The infant is normal at birth but develops jaundice and toxæmia shortly afterwards. In vessels where the circulation is sluggish agglutination takes place and thrombi form—the nature of the signs depending on the location of the latter. The liver is almost invariably affected. Erythroblastæmia is due to thrombi in the bone marrow, not necessarily accompanied by anaemia, and kernicterus is the outcome of a blockage of vessels in the brain. When similar symptoms occasionally occur as a result of univalent antibodies it may be because the infant is dehydrated, with consequent premature formation of X-protein and co-glutination. Other cases may rarely occur as a result of AB or Hr sensitization. Transfusion is useless in this group.

The second group—congenital haemolytic disease—is, Wiener and Brody state, caused by univalent Rh antibodies which because of their smallness pass into the foetal circulation during pregnancy and produce “coating” and rapid breakdown of the foetal red cells, thus causing a progressive anaemia and, in severe cases, stillbirth and hydrops foetalis. In this group the foetal antibody titre more closely approximates to that of the mother, and the severity of the disease corresponds to the height of the maternal titre. Kernicterus is not a common sequel, and, if they recover, the infants usually develop normally. Transfusion with Rh-negative blood of a suitable group is the best treatment.

In the third group—icterus praecox—maternal *alpha* or *beta* antibodies act as lethal agents on the red cells of infants with an incompatible blood group, a pathological extension of what has often been termed the “physiological” icterus of the newborn. Typical cases develop a greater or less degree of jaundice in a few days and clear up spontaneously.

In effect Wiener and Brody distinguish between bivalent and univalent antibodies produced as a result of sensitization of an Rh-negative mother by an Rh-positive foetus. They consider that the bivalent antibodies may as a result of thrombosis cause jaundice, erythroblastæmia without anaemia, and kernicterus, though in any one case all three conditions may not be present. The univalent antibody on the other hand causes haemolysis of the foetal red cells, jaundice, and anaemia, and in this group alone is transfusion of any value. From the practical standpoint they claim that by differentiating these two types of rhesus antibody in the mother the chances of kernicterus occurring in any given case can be foreseen even before birth.

This new theory receives striking confirmation from the work of V. C. Vaughan,¹ who studied erythroblastosis foetalis and the incidence of kernicterus in 72 infants. He confirmed the fact that cases of kernicterus tended not to develop gross anaemia and that indeed anaemia was sometimes conspicuous by its absence. While refusing to commit himself regarding the actual pathology and the serological mechanism of the condition, he agrees with Wiener and Brody that transfusion with Rh-negative blood is useless for this type of erythroblastosis, and is even inclined to advocate the trial of Rh-positive transfusion as a “challenge” for antibody transferred to the foetus during

Clearly no final conclusion has been reached, but these findings are important, and they serve as another example of the need for backing laboratory hypotheses by clinical observations.

PROTEIN DEPLETION AND RESISTANCE TO INFECTION

Does an inadequate diet adversely affect the capacity to respond to artificial immunization? This question is of topical importance, and in answer to it recent observations of Wissler² are of interest. He compared the response of groups of rabbits on a normal diet to two intravenous injections of a pneumococcal vaccine with that of groups kept for a long period on a diet containing one-seventh to one-fourteenth the amount of protein. Type I pneumococcus was chosen because rabbits are highly susceptible to this organism but can normally be readily immunized against it. The resistance of the animals to the intradermal injection of an infecting dose of pneumococci was tested six days after the last dose of vaccine.

The rabbits on the low-protein, low-calorie diet were lighter than the controls, lost hair and fat, and sometimes had ascites and hydrothorax; they were anaemic and had low serum-protein levels, due to deficiency of the albumin fraction; the total leucocyte count was unchanged, but there was some increase of granulocytes and decrease of lymphocytes. The average agglutinin response of groups of young and adult rabbits on the defective diet was much lower than in the normal group. In the former groups only 1 out of 13 adults and 2 out of 14 young animals survived the challenging dose, as compared with 6 out of 10 and 17 out of 19 in the corresponding control groups. The survival times of non-immunized rabbits of the various groups did not differ significantly. There was excellent correlation between a certain level of agglutinins and survival. The protein-depleted animals had only a small rise in the granulocyte count and a steep fall in serum-protein concentration during infection. In the rabbits with low resistance the skin lesion was spreading and oedematous, and, in contrast to the findings in adequately immunized animals, scanty interstitial agglutination and phagocytosis of the pneumococci were observed in it.

Similar results were obtained in a series of experiments with rats in which the infecting dose was adjusted according to body weight. When the quantity of food eaten was equalized in the low-protein and control groups the agglutinin response in the two did not differ, but the relative survival rates were similar to those obtained with rabbits. Unlike rabbits, rats possess some degree of natural resistance to pneumococcal infection, which was largely lost during protein-depletion. Mouse-protection studies failed to reveal any circulating antibody to explain this resistance, the loss of which could be counteracted by passive immunization sufficient to raise the agglutinin titre to the level usually obtained by active immunization of rats on the control diet. As with rabbits, the degree of natural and acquired resistance was related to the effectiveness of phagocytosis.

Under the conditions of these experiments it was much more difficult to produce resistance to infection by artificial immunization in animals kept on a grossly protein-deficient diet than in normal animals. This ineffective resistance was associated with a poorer humoral antibody response and probably with an impaired production of leucocytes following infection.

NATIONAL HEALTH SERVICE ACT, 1946

POSITION OF CONSULTANTS AND SPECIALISTS*

OPINION BY COUNSEL

I have been asked to advise as to the position of consultants and specialists (hereafter called specialists) under the National Health Service Act, taking into account the questions submitted to the Minister by the B.M.A. and the replies of the Minister thereto.

The duty rests upon the Minister to provide the services of specialists at a hospital, health centre or clinic, or, if necessary on medical grounds, at the home of the patient. (Under Section 3.) The position of specialists under the Act is uncertain and in my view unsatisfactory, inasmuch as their rights and obligations are largely left to be determined by Regulations to be made by the Minister. (Sections 68 and 14.) No Regulations dealing with provision of specialist services under the Act have yet been made, and until such Regulations are made and published it is not possible to form any opinion whether specialists will be offered fair and equitable treatment under the Act.

I suggest that a request should be made to the Minister to consult the London Consultants Liaison Committee before he makes any Regulations as to specialist services under the Act.

1. Specialists Holding Appointments at Hospitals Immediately Before the Appointed Day

There is a marked distinction between the provisions of the Act as to general medical practitioners who wish to provide general medical services under the Act and specialists who hold an appointment at a hospital on the appointed day and who wish to provide specialist services under the Act.

Every medical practitioner who is engaged in medical practice (otherwise than as a paid assistant) is entitled under the Act, as of right, to have his name included in the list of medical practitioners undertaking to provide general medical services in his area if he makes an application at any time before the appointed day. (Section 34, Subsection 1.) There is no provision in the Act giving a similar right to a specialist holding an appointment at a hospital on the appointed day.

It is enacted by Section 68 that Regulations shall provide for the transfer and compensation of certain officers therein specified. Until, therefore, the Regulations are made, the position of specialists holding appointments at hospitals and particularly of honorary specialists is uncertain.

I interpret Section 68 (1) as meaning that, under the Regulations when made, all specialists (except possibly honorary officers) holding appointments, whether part-time or whole-time, at a transferred hospital immediately before the appointed day will be transferred in the case of a non-teaching hospital to the Regional Hospital Board, and in the case of a teaching hospital to the Board of Governors. I am not quite sure, however, whether the words "employed solely or mainly at or for the purposes of a hospital" are intended to cover a part-time appointment.

There is no provision in the Act which guarantees to specialists (whether whole-time or part-time) that, on transfer, they will be employed on terms and conditions and in circumstances not less advantageous than were applicable to their existing appointment at the date of the transfer.

There is no provision in the Act which would prevent the Regional Hospital Board or the Board of Governors from terminating the appointment of a specialist, after transfer, on short notice, or from compelling such specialist to relinquish his appointment by reason of his being required to perform duties which were not analogous with or which were an unreasonable addition to those which he was required to perform immediately before he was transferred.

There is no provision in the Act entitling the specialist (except some in whole-time employment) whose appointment is so terminated or relinquished to compensation for loss.

*Issued by the subcommittee of the London Consultants Liaison Committee: Lord Horder (Chairman); Sir Reginald Watson-Jones; Dr. Geoffrey Bourne; Mr. A. Lawrence Abel; Mr. Eric Steeler (Secretary).

The answer of the Minister to Question 6 shows that he contemplates that on the appointed day the existing staffs of hospitals will be taken over by the Regional Hospital Boards or the Boards of Teaching Hospitals. It is not quite clear from the answer whether "staffs" includes part-time specialists or honorary specialists. It is clear, however, from the answer that the Regional Hospital Board and the Board of Governors of Teaching Hospitals will be expected by the Minister to review the services of their regions and to offer new appointments to their staffs either in their existing or in other hospitals.

On transfer, therefore, a specialist will merely hold a temporary appointment until he is offered a new appointment at the same or another hospital on such terms and conditions as the Board determine (subject to any Regulation made by the Minister).

In my opinion neither the provisions of the Act nor the answer of the Minister can be regarded as satisfactory or as affording such reasonable protection as specialists now holding appointments at hospitals can fairly claim.

I advise that every effort should be made to obtain in the Amending Act provisions similar to Sections 58, 59, and 60 of the Health Services Bill (Northern Ireland).

"Section 58. (1) All officers employed immediately before the appointed day solely or mainly at or for the purposes of any hospital transferred to the Authority under Section 23 of this Act shall on that day become by virtue of this section officers of the Authority.

"Provided that the foregoing provisions of this section shall not apply to:

(a) any person who has attained the age of 65 years on the day immediately preceding the appointed day;

(b) any person who elects in the prescribed manner that they shall not apply to him.

(c) honorary officers.

"(2) An officer of any hospital who by virtue of the foregoing provisions of this section, becomes an officer of the Authority shall be employed by the Authority on terms and conditions (including conditions as to superannuation benefits) and in circumstances not less advantageous than were applicable to his employment with that hospital:

(a) on the twenty-first day of March, 1946, or

(b) where such officer was not employed by the hospital on that date, on the day on which he entered that employment.

"(3) Where, in any case to which paragraph (a) of the last preceding subsection applies, the terms and conditions applicable to the employment become, after the date specified in the said paragraph, more advantageous to the officer by reason of any increase of salary or other additional benefit, the Ministry may, if it thinks fit, direct that the right to that increase or benefit shall be included among the terms and conditions on which the officer is employed by the Authority; and where such a direction is given with respect to any officer the provisions of the last preceding subsection shall in relation to that officer have effect subject to the said direction."

"Section 60, Subsection (2). Subject to the provisions of this section, every officer employed by the Authority or the Board:

(a) who became such an officer by virtue of the provisions of Section 58 of this Act; and

(b) who within five years of becoming such an officer:

(i) relinquishes office by reason of his having been required to perform duties which are not analogous with or which are an unreasonable addition to those which he was required to perform immediately before he became such an officer;

(ii) from any cause other than misconduct or incapacity or his having attained the age of 65 years is removed from or required to relinquish office;

shall be deemed, unless the contrary is shown, to have suffered a direct pecuniary loss in consequence of this Act, and shall be entitled to compensation under this Act for that loss. Compensation under this subsection shall be payable by the body by whom the officer was employed as part of the expenses of the Authority or the Board as the case may be."

I also advise a definition of the words "officers employed." (Section 68 of the Act.)

SPECIALISTS HOLDING "HONORARY" APPOINTMENTS IMMEDIATELY BEFORE THE APPOINTED DAY

As I have pointed out, the Regulations as to transfer which will be made by the Minister under Section 68 may contain exceptions and conditions in the case of honorary officers.

I gather, however, from the Minister's answer to Question 6 (though it is not quite clear) that specialists holding honorary appointments will be transferred to and become officers of the Regional Hospital Board if they consent to such transfer.

It appears from such an answer that they will then be offered a new appointment at their existing or other hospitals which (the new appointment) they will be free to accept or refuse. I apprehend that the terms and conditions of service will be similar to those applicable to a paid appointment except as to the emoluments.

It might, for example, happen that a specialist holding an appointment at Bristol be offered an appointment at Truro because of redundancy at Bristol. If, however, the new appointment were refused, it appears that the specialist would not be allowed to retain his existing appointment, and he might not be offered any alternative appointment.

In my opinion the safeguards which I have suggested with regard to whole- or part-time paid specialists should also apply to existing honorary specialists.

Another question which requires consideration is the possibility that in the course of time Regional Hospital Boards or Boards of Governors might tend to appoint more whole-time specialists and fewer part-time specialists until the majority or possibly the whole of such appointments were whole-time.

I cannot find anything in the Act which would preclude the Boards from adopting this course if they were or became minded to do so.

On the other hand, the Minister in several of his answers states that he anticipates that consultant and specialist appointments at hospitals should in most cases be part-time. He also states that if any Regulations are made under Section 66 he will exclude from them any provision of universal whole-time specialist services.

I advise that the specialists should ensure that the Amending Act implements the Minister's promise that hospital appointments for specialist staff will usually be part-time, so that the specialist service cannot become a whole-time service by Regulation.

COMPENSATION

The only persons who are entitled under the Act to be paid compensation are the persons specified in Section 68 (e) and 68 (1) (f). One of the essential qualifications is whole-time employment.

The right to compensation, however, is not conferred by an express clause in the Act itself, but will be governed by Regulations which are to be made by the Minister and which may contain exceptions or conditions. (Section 68.)

Moreover, the Act is silent as to the method of making a claim, the person or body by whom the claim is to be determined, the procedure for determining a claim, and to the right of appeal on fact or on law. Presumably the Minister proposes to provide for all these matters by Regulation.

I advise that the right to compensation should be conferred expressly by a separate clause in the Amending Act, and that this clause should contain provisions as to the determination of such claims by a Claims Tribunal and regulating the procedure upon the lines of Section 60 and the Sixth Schedule to the Irish Bill.

Inasmuch as the ordinary part-time specialist, honorary or paid, is not entitled to compensation, it is essential that he should be assured of security of tenure of his office with its attendant facilities.

2. Appointment of Specialists to Hospitals

In the event of a vacancy for a specialist at a hospital after the appointed day, the appointment will be made by the Regional Hospital Board in the case of a non-teaching hospital, and by the Board of Governors in the case of a teaching

hospital from persons selected by an Advisory Appointments Committee. (Section 14.)

The Minister, however, has power to determine by Regulation what classes of medical officers shall be appointed. (Section 14.)

The Advisory Appointments Committee will be established under Regulations and will consist (1) in the case of a non-teaching hospital of persons nominated by the Regional Hospital Board and the Hospital Management Committee of the hospital affected, and (2) in the case of a teaching hospital of persons nominated by the Board of Governors and the University with which the hospital is associated.

The representatives of the medical profession will be in a minority upon the Regional Hospital Board and the Hospital Management Committee.

There is therefore no guarantee that, on the occasion of a vacancy at a hospital, any specialists of the class of specialists concerned will be members of the Advisory Appointments Committee. Also there is nothing in the Act that obliges the Appointments Committee to consult the existing staff before making any selection for a new appointment.

I advise that the Act should be amended so as to provide: (a) that in the case of an appointment involving specialist services the Advisory Appointments Committee should include a specialist or specialists nominated by any organization which appears to the Regional Hospital Board or Board of Governors to be representative of the class of specialists concerned; (b) that before making their selection the Advisory Appointments Committee should consider any recommendations made by the specialists then holding appointments at the hospital affected.

3. Legal Rights of a Specialist on Appointment to a Hospital

On appointment to a hospital the specialist becomes an officer of the Regional Hospital Board or of a Board of Governors. His remuneration and conditions of service will be fixed by the appropriate Board, subject to Regulations made by the Minister. Presumably the specialist will be required to enter into a contract with the Board laid down by the Minister. The specialist's rights will depend on and be defined by that contract.

I advise that the Minister should be asked to state the terms of the contract, and in particular its duration, the rights of the Board to terminate it, and the grounds upon which the same may be terminated.

I advise that following the present practice the engagement should be until the attainment of an agreed age, terminated only for misconduct or incapacity.

I advise that the Minister should be asked to provide in an Amending Act that the specialist should have the right to appeal to a Tribunal comparable to that under Section 42, with an ultimate right of appeal to the High Court.

I have considered the latter half of the Minister's reply to Question 6, but in my view it does not provide adequate protection. Of course, if there is a breach of contract the specialist would have his remedy at law. If, however, the contract provides that it may be terminated by the Board by notice of a specified length, the Board could lawfully terminate the contract at the expiration of such notice without assigning any reason. Neither the Medical Committee nor a Whitley organization could, in my view, provide an adequate remedy against a capricious determination of the contract by the Board.

SPECIALISTS PROVIDING SPECIALIST SERVICES AT A LOCAL HEALTH CENTRE, CLINIC, OR AT THE HOME OF A PATIENT (SECTION 21, SUBSECTION 2)

It is not clear whether the "staff" whom a local health authority are required to provide at a Health Centre for specialist services will be employed by the local health authority or by the Regional Hospital Board or Board of Governors. Moreover the Act does not clearly indicate the person or body by whom a specialist will be employed for the purpose of providing specialist services at a clinic or at the home of the patient. Possibly the intention of the Minister is that all such specialists shall be employed by the Board of a hospital, but it is desirable that the position should be made clear.

4. Preservation of Existing Pay-beds in Hospitals

There is no obligation under the Act upon the Minister to preserve existing pay-beds in hospitals. Under Section 5 he may do so if, having regard to his duty to provide hospital and specialist services, he is satisfied it is reasonable. The Minister may allow any medical practitioner whether honorary or paid on the staff of a hospital providing hospital and specialist services to treat his private patients at that hospital or at any such other hospital and may make available such special accommodation. In this event the patient pays the cost of the special accommodation and the fees to the specialist not exceeding the maximum fee prescribed by Regulations.

In his answer to Question 2 the Minister says that private pay-bed accommodation is promised under the scheme and expressly provided for in the Act, and that it is to be assumed that at the outset of the scheme it will lie where it is at present, but the Minister cannot tie himself to an exact future distribution now. The Minister adds that the continuance of part-time specialists at hospitals accords with the intention of the scheme and there will therefore be facilities for them.

The existence of private pay-beds at hospitals is of fundamental importance to specialists, and I advise that a clause should be inserted in the Amending Act similar to Section 29 (2) (f) and 29 (2) (g) of the Irish Bill ensuring the preservation of such accommodation where it exists.

It is possible that after the appointed day the hospital accommodation will be found to be inadequate to meet the demand for non-paying beds and it is in my view likely that, notwithstanding the intentions of the Minister and of the scheme, the existing pay-beds may be utilized to meet the demand for non-paying beds. The Minister could shelter himself under the opening words of Section 5 if he found himself constrained to take this course.

I advise that the Amending Act should include a provision on the lines of Section 21 (4) of the Irish Act so as to make it clear that a hospital is entitled to establish new pay-beds.

5. Retention and/or Establishment of Medical Committees in Transferred Hospitals

Though there is power under Section 12 to appoint Medical Committees in hospitals subject to Regulations and directions given by the Minister, there is no express provision in the Act for the appointment of such Committees. It is clear, however, from the Minister's answer to Question 4 that he entirely agrees with the system of Medical Committees in hospitals and has expressed his view to Regional Hospital Boards and Hospital Management Committees and asked that every encouragement and facility should be given to this system.

Under the Act the medical staff of a teaching hospital has the right to nominate not more than one-fifth of the Board of Governors. No similar right is accorded to the staffs in the case of a non-teaching hospital or group of hospitals to nominate members to the Hospital Management Committee.

The Act merely provides that the Regional Hospital Board shall consult the medical staff and appoint some members of the Hospital Management Committee without being bound to accept their nominees. This might result in there being no representatives of the medical staff on the Hospital Management Committee.

I advise that the medical staffs of non-teaching hospitals should be accorded the same rights of nomination as have the medical staffs of teaching hospitals.

6. Acquisition of Land (Section 58)

The power of the Minister and of a local authority to acquire land compulsorily includes the power to acquire a hospital or clinic or nursing-home carried on for profit.

I advise that Section 58, Subsections (1) and (2), should be amended so as to exclude a "hospital" carried on for profit as is contained in the Irish Bill. (Section 67 (1).)

7. Freedom of Speech and Publication

By his answer to Question 5 the Minister states that the assurances already given cover complete freedom to publish views on the organization and administration of the Service as

well as on clinical matters without obtaining any prior consent to do so. I understand that the Minister has declared his intention to incorporate a clause to this effect into the contracts of medical practitioners who undertake to provide any services under the Act. This is an important matter upon which the profession as a whole should come to a decision.

If the assurance of the Minister is implemented by a suitable provision in the contract of each medical practitioner (whether providing specialist or general medical services) he will for all practical purposes be as well protected as if there was a clause in the Act.

The prejudice which a medical practitioner would be most likely to suffer as a result of his public criticism of the Service would be that his contract might be terminated by the body which employs him. If the contract contains an appropriate clause (as promised by the Minister) public criticism of the Service could not be construed as misconduct which would entitle the employing body to dismiss summarily the medical practitioner. It is possible that the employing body might as a result of such criticism seek to terminate the contract of a medical practitioner without disclosing the real grounds for terminating the contract. This, however, might happen whether there is a clause in the Act or not.

I have already made some suggestions for the protection of specialists against a capricious determination of their contracts. The profession must decide whether they are prepared to rely upon the repeated assurances of the Minister on this question, knowing that there is no provision to this effect in the Act or in the Regulations published up to date.

Regulations (Section 75)

One of the most unsatisfactory features of the Act is that many of the important matters arising under it are not enacted in the body of the Act, but are left to be governed by Regulations. The Minister has very wide powers to make Regulations, and is not under any statutory obligation to consult the medical profession before he makes such Regulations.

I have already pointed out that the rights and obligations of specialists will be almost exclusively determined by or in accordance with Regulations.

I have considered the Minister's answer to Question 7. It is quite true that Regulations have certain advantages where flexibility is required. On the other hand they might equally be used to reduce as well as to increase the capitation fee of general medical practitioners or the emoluments of specialists, or to impose upon them more onerous duties or unfavourable conditions of service. Moreover, as Regulations may be modified or repealed by the Minister, where the existing rights of individuals are affected by the Act, they enjoy greater protection if the Act contains specific clauses defining those rights. I have already indicated some instances.

As to the Minister's power to make Regulations, I think that possibly the College of Physicians had in mind Section 1 of the Rules Publication Act, 1893. The application of this section to Regulations made under this Act is expressly excluded. (Section 73 (5).)

Under Section 1 of the Rules Publication Act, 1893, a Minister is required (*inter alia*) to give forty days' notice in the *London Gazette* of his intention to make Regulations. Any public body may inspect the draft Regulations and the Minister is required to consider the written representation of any public body interested before he makes the Regulations.

I advise that the Minister should be approached with a view to securing an amendment which provides that Section 1 of the Rules Publication Act, 1893 (or a suitable modification thereof), should apply to Regulations made by the Minister in future.

The Royal Colleges and the B.M.A. should be included in the definition of "public body" so as to enable them to inspect the draft Rules and to have the right of making representations.

Under the present procedure in Parliament, Regulations are seldom debated or submitted to detailed examination by the House unless the Special Committee recommends that the special attention of Members should be drawn to them.

Under this Act the power of the Minister is so wide and the area over which the power extends is so large that it is difficult to imagine any Regulation which could go beyond the scope of the Act.

SPECIALISTS AND THE NEW SERVICE

LONDON MEETING

A meeting of consultants and specialists of London and the Home Counties, summoned by the Marylebone Division of the British Medical Association, was held in the Great Hall, Tavistock Square, on April 22. The purpose was to consider the present position in view of the recent conversations with the Minister. There was an attendance of over 200. Mr. A. M. A. Moore presided.

The Recent Conversations

Lord Horder, who was one of the deputation to Mr. Bevan on April 12, said that it was a very friendly interview up to a certain point. The Minister was extremely conciliatory, obviously anxious that doctors should enter the Service, but his answers to a number of the questions (which Lord Horder thought not too well chosen) were evasive, and at the end it did not appear that the main position had changed materially. Certain small points were conceded, but always when it came to fundamentals—that is to say, the terrifically powerful position the Minister maintained in respect of a comprehensive service—the answer was in the negative. He himself would have liked more attention paid to the last question of all put to the Minister—namely, whether he agreed that the appointment of members of the profession to administrative and other bodies should be in consultation and agreement with representative bodies of the profession. The answer was that the Minister was ready to consult, but constitutionally the decision was his. At the conclusion of the questions the Minister asked Dr. Dain whether he would now be prepared to advise the profession to enter the Service. Dr. Dain wisely declined the invitation to give an immediate answer, and said that this was a sum in arithmetic and that he must take time to add it all up. The dictator then made himself obvious, and suggested that the blame for delay must be laid at the door of the B.M.A. and not at his own.

Since then there had been an "extraordinary hustle" over the second plebiscite. It was rather beating the air to discuss anything that evening except the position of specialists (a generic word for both specialists and consultants). General practitioners would make up their own minds in the plebiscite now being taken, but there remained a definite interest for the specialist apart altogether from the general practitioner. In his own view the general practitioner's freedom had not been safeguarded; he was being outwitted by political manœuvring. But as for the specialist, his position was as yet wholly undefined. The Act gave the Minister power to set up a specialist service in or out of hospital, but the terms of contract were not known. Therefore, although they would vote in the plebiscite—he would vote in the same way as he had done before, the position being in his judgment not virtually changed—he thought they had also to look at their own house and see if it was in order.

It was highly desirable (Lord Horder continued) that as soon as possible specialists should have a policy either to do something or to refrain from doing something until their knowledge of where they stood was more complete. He suggested that they should say to the Minister, "You have so far laid down no conditions of service in or out of hospital." He himself would stand very strongly for the availability of the specialist for domiciliary purposes if the doctor in charge of the case wanted help. But in or out of hospital the position was still entirely indefinite.

Lord Horder went on to refer to the setting up of the London Consultants Liaison Committee, whose first task it had been to discover where, legally, specialists stood under the Act. The opinion of Mr. Cecil Havers, K.C., had been sought, and copies of this opinion, fresh from the printer, had been distributed among those attending the meeting. Lord Horder urged that no contract be signed and no payment accepted until there was an agreed policy between a representative body of specialists and the Minister. (Applause.)

Mr. Naughton Morgan said that the overwhelming vote against the Act as shown in the last plebiscite was not a vote against the details of the Act were too complicated and

abstruse for most of them to follow—but it was a vote of conscience against what had been done. He drew attention to one statement by Mr. Cecil Havers in the opinion just mentioned:

The position of specialists under the Act is uncertain and, in my view, unsatisfactory, inasmuch as their rights and obligations are largely left to be determined by Regulations to be made by the Minister.

Until Regulations dealing with the provision of specialist services were made and published it was not possible to form any opinion whether specialists would be offered fair and equitable treatment under the Act.

Dr. E. C. Warner regretted that they had conceded the position with regard to the administration of voluntary hospitals. A scheme might have been worked out on a very different basis. Why should not the large hospitals have been placed in a similar position with regard to grants to that which obtained in the medical schools? They might have been given a State grant and allowed to administer it in their own way without hordes of officials being appointed to see how it was spent. The scheme of the University Grants Committee might have been applied in a larger sense. The Service came into operation in ten weeks' time, and yet specialists had not been given one word of help as to the nature of the scheme under which they had to work. Many things had to be clarified. Was it going to be possible for a consultant outside the Service to use hospital beds at all even in the private wards? Another point was that, on transfer, as Mr. Havers said, a specialist would merely hold a temporary appointment until he was offered a new one at the same or another hospital on such terms and conditions as the Regional Hospital Board determined. The Minister seemed to have adopted a more conciliatory attitude towards general practitioners than towards specialists. The speaker was anxious that they should not sell their birthright and the interests of their patients for a scheme over which they had no control whatever. Until they knew what the conditions of service were going to be, he did not feel that he could vote in the present plebiscite differently from the way in which he voted in the last.

Legal Opinion

Mr. Lawrence Abel reminded the meeting that, very largely due to the efforts of their chairman, Mr. A. M. A. Moore, a democratic scheme for the representation of all consultants and specialists had been brought forward and approved by the Council of the British Medical Association. He then gave a review of Mr. Cecil Havers's opinion which the London Liaison Committee had obtained. One point made by Mr. Havers was that every effort should be made to obtain in the Amending Act provisions similar to certain sections of the Northern Ireland Act, whereby every consultant, like every general practitioner, had the right to enter the Service if he wished. Mr. Havers also advised that specialists should ensure that the Amending Act implemented the Minister's promise that hospital appointments for specialist staff would usually be part-time, so that the specialist service could not become a whole-time service by regulation. Again, inasmuch as the ordinary part-time consultant (honorary or paid) was not entitled to compensation, Mr. Havers advised that it was essential he should be assured of security of tenure of his office with existing facilities. As to the legal rights of a specialist on appointment to a hospital, Mr. Havers advised that the Minister be asked to state the terms of the contract, and in particular its duration, the rights of the Board to terminate it, and the grounds upon which it might be terminated; that, following the present practice, the engagement should be until the attainment of an agreed age, terminable only for misconduct or incapacity, and that the Minister should be asked to provide in the Amending Act that the specialist should have the right to a tribunal comparable to that under Section 42 of the Act, with an ultimate right of appeal to the High Court. A clause should be inserted, as in the Irish Act, ensuring the preservation of private pay-bed accommodation where it existed, and a provision to make it clear that a hospital was entitled to establish new pay-beds. Mr. Havers was also of opinion that the medical staffs of non-teaching hospitals should be accorded the same rights of nomination to the Board of Governors as the staffs of teaching

hospitals possessed. There were several other points in this very useful opinion, many thousands of copies of which were being distributed.

A Change of View

Sir Reginald Watson-Jones said that since they last met in that hall an event had happened upon which it was difficult to speak but impossible to be silent. His meditations had led him to a certain conclusion. For two years he had persisted relentlessly and without faltering in his opposition to the National Health Service Act, which, he had believed, threatened the freedom of medicine. At a dinner over which he presided, when Mr. Attlee and Mr. Bevan were guests, he had declared: "I will not be a Civil Servant." During those two years he had spoken at meetings of the Council of the Royal College of Surgeons, sometimes in a majority, sometimes in a minority, once at least in a minority of one. Finally he had been and still was a trustee of the Independence Fund. With that background, if the conclusion at which he had arrived was that they should now accept service under the new Act, he trusted it would be accepted that he was no quivering, or one afraid of being in a minority, or one who, before he spoke, considered his personal advantage.

What was it for which they had been fighting, and how far had they succeeded? They had been fighting for the freedom of medicine, professional freedom, freedom from bureaucratic control, freedom to speak and publish and criticize, freedom for the pioneer, freedom for private practice alongside nationalized service. How far in the promise of an Amending Act had they succeeded? They had succeeded in that there would now be medical committees for every hospital: the medical committees of teaching hospitals would nominate their own representatives on governing boards, and although it was different with the non-teaching hospitals he believed that their representatives would be appointed too. They had succeeded in the matter of freedom of speech and publication, relating to administrative as well as clinical matters. They had the promise of an Amending Act to ensure that a whole-time State salaried service would not be brought in by Regulation. Their freedom was no longer threatened.

On what points had they failed? They had failed in securing the exclusion of the power of compulsory purchase of hospitals and nursing-homes carried on for profit. He would have liked to see a provision such as had been introduced in the Irish Bill making such acquisition impossible, but he could not agree with those who said that this compulsory acquisition would be a way of destroying private practice. Such destruction would not come about by acquiring the building but by acquiring the surgeon. They had failed in another matter. Staff appointments would be made not by medical but by appointments committees: but was that an important principle, or was it one on which they might have two views? They had failed to secure a firm promise of security of tenure of a surgeon in his present post. But he wondered whether that was an object which they could expect to achieve.

He submitted that the points on which they had succeeded were points of principle, and the points on which they had failed were points of detail. Two months ago when the consultants and specialists held a meeting in that hall they were considering fundamentals. Fundamental principles had been challenged, and the plebiscite, with its 94% "No" vote, was the answer. They were now considering debatable details.

"We have won a most resounding victory. From the lack of enthusiasm here to-night I begin to wonder whether that is true. But the most important point is that we have demonstrated that the profession when united can alter the decision of a Minister and a Government. I agree with what Mr. David Eccles, M.P., says in *The Times* this morning: 'The doctors have learned the secret of this power [the power of a united profession] and if they use it wisely and do not throw it away by splitting on unpopular issues they can stand up to this Minister and any of his successors.'

"Our duty now is twofold—first, to say that we acknowledge the concessions which have been made and accept the assurances, and secondly, and no less important, to watch every Regulation that is issued and to see in fact that these promises are implemented."

The speaker quoted a passage from Edmund Burke, and added: "We have achieved a victory which has determined our liberty; let us now achieve the order without which that victory means nothing."

Stipulations before Agreement

Dr. Geoffrey Evans said that it was a pyrrhic victory which had been won. He recalled that in 1929, when he was honorary secretary of the London Voluntary Hospitals Committee, pains were taken to secure for voluntary hospitals an equal status with municipal hospitals, and after conversations with Mr. Neville Chamberlain, then Minister of Health, a clause was inserted in the Local Government Act, 1929, that if there were extensions of beds in municipal hospitals they should be made in consultation with voluntary hospitals and vice versa, so that the hospital service of London might go forward in a co-ordinated manner. But when the Act was passed it was found that the clauses inserted had a legal interpretation which was not what the Minister nor they themselves had intended. They must suppose that the Minister of Health had good intentions, but he thought it ominous that eleven weeks before the Service was due to begin specialists were in ignorance as to their position. He felt that they should withhold service until what they required was in writing, and that in writing they should secure the position set out by Mr. Havers with regard to specialists holding honorary appointments immediately before the appointed day, the preservation of existing pay-beds in hospitals, the rights of nomination by medical staffs of non-teaching as of teaching hospitals, and freedom of speech and publication.

Mr. Dickson Wright said he was unable to see that the Minister had offered them anything of real value in these new conversations. It was not possible for the Minister to give the assurances asked of him. There were already a large number of whole-time people in the Service, and there was nothing to prevent a Minister increasing the whole-timers to the detriment of the part-timers, until perhaps he had ninety-nine of the former to one of the other, when he could still say that he had not gone back on his word. The voluntary hospitals could well have carried on. It was not fair to say that they had failed. The truth was that the Government had ruined them by Regulations and finance and undermined their subscription income. He did not think medical committees of the slightest value if they did not elect members of the staff: they merely became grouching bodies.

Dr. Geoffrey Bourns said he respected everything about Sir Reginald Watson-Jones except his credulity. No politician could go further than the first few steps of his career unless he learned how to change with the wind. Supposing the Service came into operation, people would soon be asking: "Where are the specialists whom we are told we could call in? Where are the health centres?" There would not be enough specialists to go round, and by Regulation the Minister would say to many of the part-time people: "Your contracts will be terminated in a month's time," and at the end of that month these "displaced persons" would be offered new whole-time jobs in other hospitals. The "spreading" was socialist policy, but a time would come when the spreading would prove too thin.

Mr. N. Ross Smith declared that their own safeguard was to have the principles they had fought for incorporated in the Act itself. He believed Lord Horder was right in suggesting that this move of the Minister was nothing more than a piece of political tactics. Sir Stanford Cade, while complimenting Sir Reginald Watson-Jones on his courage, said that in his belief this great "victory" was wholly a mockery. None of them were fighting for the potential pay that the Spens Committee might vote, but for their professional freedom, which he did not believe could be preserved under the existing Act without amendments to meet all the points brought forward by Lord Horder and others. If it was possible for the House of Commons in 24 hours to postpone the death penalty for five years, surely this Service could be postponed for a little beyond July 5.

Dr. G. J. Sophian said that what Mr. Bevan wanted was that they should surrender their arms whereby they defended themselves against his machinations. Mr. Jennings Marshall supported the view that they should decline to have anything to do with this Act until their own position was clearly stated. Mr. Lyle Cameron said that the previous day he had met someone just returned from Italy who had told him that the

550 MAY 1, 1948

resistance which the British doctors were putting up against regimentation was a point made by the winning side in the Italian elections.

Sir Reginald Watson-Jones, in reply to a question whether he would abide by the decision of the majority of the profession, said that he had been and still was a trustee of the Independence Fund, and if the majority of the profession did not enter the Service of course he would abide by that majority. (Applause.) His earlier observations were not the result of "credulity" but were based on an estimate of how best to make tactical use of their strength.

Lord Horder moved the following resolution:

That this meeting advises specialists not to enter into any contract under the National Health Service Acts until conditions of service have been agreed with the Minister.

This was carried by 196 votes to 1; there were 9 abstentions.

ACCIDENTAL SYPHILIS

BY

R. R. WILLCOX, M.B., B.S.

Senior Assistant, Venereal Diseases Department, St. Mary's Hospital; Physician in charge of Venereal Diseases Department, King Edward VII Hospital, Windsor

"The first step, in order that we should understand syphilis, is to recognize that it is by no means necessarily a venereal disease."—Sir Jonathan Hutchinson.

Syphilitic chancres are genital in 95% of cases, and the majority of the other 5% arise in or around the mouth, many of these lesions being acquired through predominantly sexual acts. Not more than 50 examples of non-sexual accidental infection were found in over 35,000 syphilitic patients examined (Moore, 1944). The effect of such modern statistics and of the observed behaviour of the organism outside the body is that towels, bedding, cooking utensils, drinking-vessels, pipes, and the like are now far less often blamed for spreading the disease: in this connexion glass-blowing was once considered a dangerous occupation. It is realized that for the spirochaete to remain viable for transmission the presence of moisture is necessary. In 1878 Lane wrote: "I believe, also, the use of public water-closets at railway stations, hotels, and clubs may be a not very infrequent cause." Since that time this convenient conception of the lavatory seat has fallen into almost complete disrepute, and any such excuse offered by the patient is, perhaps not openly, derided by the clinician; yet there would seem to be no reason why transfer of moist matter should not occasionally occur by this means. It is, however, universally agreed that sexual-intercourse is by far the most frequent cause and that kissing, albeit innocent, takes second place.

An example of infection by kissing was seen in the Army. A youth contracted a lip chancre on Christmas Day, when he was on sentry duty at the periphery of a remote camp in Scotland, and subsequently passed the disease in a similar manner to his fiancée. Schamberg reported oral transmission to seven young girls from one man in a kissing game (Stokes *et al.*, 1944), and there is no doubt that the larger the number of secondary syphilis the greater the danger of such infections, but with modern methods of diagnosis and treatment this danger is becoming minimized.

Chancres have been reported on almost every part of the body: digital chancres in dental surgeons, gynaecologists, midwives, and oto-rhino-laryngologists, and conjunctival varieties, are examples. Lane mentioned the case of an unhappy surgeon who had the misfortune to contract a digital chancre from an obstetrical case and was later forced to pay heavy damages for passing on the disease during another confinement. Recently I saw a primary lesion in the left axilla, and though no explanation could be found as to its presence the patient showed no suspicion.

Extragenital infection was once much more common, and if we think that syphilis and yaws are caused by the same organism, and that the former has developed from the latter,

is correct, then it must be admitted that syphilis was originally entirely extragenital, being spread by contact and possibly even by flies. Intermediate forms, in which infection still occurs predominantly by this means, exist to-day as bejel, pinta, and "irkinja"—Australian boomerang leg (Hudson, 1946).

Such intermediate forms have been reported as outbreaks in North-Western Europe. In 1694 a disease called "sibbens" raged in the West of Scotland, and blame for this was placed on Cromwell's army. It was spread not only by coition but also by contact—kissing and suckling, and through drinking-vessels and utensils. Oral lesions were as prominent as genital manifestations, but it must be borne in mind that a woman with a primary sore on the cervix might show the first obvious symptoms in the mouth. Children were also affected, many possibly by suckling. "Radesyge," "the foul disease" of Norway and Scandinavia of the eighteenth century, the spread of which was aided by the fuel-saving custom of "bundling," was believed to have been of a similar nature, as were "Amboyna pimple" of the Moluccas and "Schlerlievo" of the Adriatic coast during the nineteenth century.

In those times mercury was the only effective means of treatment, and this was often delayed until the appearance of secondary signs, so that a diagnosis of "confirmed lues" could be made. This delay, the less-advanced views concerning the advisability of bathing, and the practice of allowing wet-nurses to assist in the suckling of children were the predisposing causes of spread of the infection. In 1752, at Nerac in France, some 40 women and children, in addition to numerous male consorts, were infected as a result of transmission by wet-nurses after one had contracted a nipple chancre from a congenital syphilitic infant.

Syphilis has been inoculated deliberately "by the physician on numerous occasions. Hunter's unfortunate experiment in 1767 is perhaps the most famous; but that of Bell, who in 1792 published an account of his failure to transfer syphilis to three medical students smeared subreptitiously with gonococcal pus and his subsequent success with two students when syphilitic matter was applied, deserves fuller mention. Wallace, in 1835, infected five healthy persons with matter from a secondary syphilitic, and thus proved that this stage of the disease was indeed infectious—a fact which Hunter and Ricord, as a result of more cautious lukewarm experiments confined to those already infected, had previously erroneously denied. Similar experiments also proved the infectivity of blood, and the prophylactic action of mercury was vividly demonstrated by the human experiments of Metchnikoff.

Apart from these calculated performances, the medical profession has been responsible for its fair share of the spread of extragenital infections. Cupping, as part of the ritual of celebration of St. Luke's Day, accounted for 180 cases at Brno, in Moravia, in 1578; though cynics will suggest some other feature of the celebrations as the most likely cause. In Hunter's time cases arose after transplanting teeth—a practice then in vogue. If the transfer was made too soon, or from a living person, a chancre occasionally developed after an appropriate interval in the socket of the recipient.

Vaccination was another great source of infection, and by employing the arm-to-arm technique the presence of an infectious syphilitic infant early in the chain might have serious results. Lancereaux (1868) referred to 351 persons known to have been inoculated with tainted serum; of these 258 contracted the disease. In 1870 Hutchinson published a series in which 10 out of 12 children were affected, and two years later a further series showing 15 possible infections out of 26. In one series of 46 most of the children, with their mothers—not to mention the fathers—became afflicted, and there were 19 deaths among the children. To-day this kind of tragedy is almost unknown, and the possibility is scarcely taught to the rising generation of medical students, though the textbooks used by our fathers contained tables of differential diagnoses concerning vaccinal syphilis. I have seen a primary yaw develop in a vaccination site, but it is to be hoped that the two infections were not acquired simultaneously.

Eustachian catheterization was another cause, and at a meeting in Paris in 1861 13 cases due to this procedure were reported. In more recent times blood transfusion has occasionally been a means of transmission, even during the incubation period of

the disease (Moore, 1944). Tattooing also has produced an occasional case. Hutchinson (1905) published a startling photograph of three chancres developing in the forearm over a tattoo mark of the Crucifixion. The Jewish rite of circumcision has also produced oral lesions in the rabbi, and the spitting of disinfectants has caused the reverse at a precocious age in the subject. Murrell and Gray (1947) described five cases of acquired syphilis in children at Edinburgh and those of two adults who contracted extragenital lesions as a result of fondling a congenital syphilitic infant. One child, prone to sucking things, was said to have found a condom in the park—a mode of infection also cited by Stokes.

The rather flimsy excuse for writing this article has been the recent experience of a lip chancre in a young woman obtained from her fiancé, who apparently had also obtained the infection by innocent means, though this is by no means completely proved.

The woman, a virgin aged 25, had had a chancre on the upper lip for nearly four months before she was referred for treatment, by which time she showed well-marked secondary signs of rash, adenitis, condylomata about the anus, and mucous patches on the vulva and lower lip. *Treponema pallidum* was recovered from the condylomata, and the serology was strongly positive. She denied any history of intercourse, though she had recently warmly welcomed her fiancé after his return from the Far East. He gave a history of intercourse in Java just over twelve months before, but two months later a serological test gave negative results. He was now well and no signs were detected. The serology both Wassermann and Kahn, proved strongly positive, and detailed questioning revealed that ten months previously he had struck a man in the teeth with his fist and had broken the skin. This wound went septic, and though dressed at hospital with frequent antiseptics it refused to heal for six weeks, the turning-point being the application of penicillin cream in the fourth week. A well-marked cicatrix on the knuckle of the right hand was shown in evidence, and the epirochlear gland on that side was just palpable. I had previously seen and her patient from the same area who had been infected by a bite on his chest from a native.

These examples are cited to show: (1) that non-sexual transmission is no great rarity; (2) that there is no reason for not giving the benefit of the doubt to persons with a positive serology who deny all history of previous genital disease or of sexual intercourse; and (3) that the possibility of extragenital infection—yes, even the water-closet seat—should be accepted at least in women and not conceded as a favour with the tongue in the cheek.

were chosen, so far as possible, to provide a random sample from selected areas. Visits were also made to a few selected pharmacies giving a comprehensive service of the highest class, and to pricing bureaux. No inquiries were made into dispensing done under contract with doctors, dispensing done for institutions such as hospitals and infirmaries, and "counter prescribing." The four pharmacists in the Working Party were divided into two teams, each team containing one representative of England and Wales, and one of Scotland. A trial tour was made initially in Devon and Cornwall. A questionnaire was also sent to certain pharmacies not visited.

Formularies and Standardization

The Working Party points out that it is generally claimed that there is less use of formularies in Scotland than in England and Wales, and broadly speaking it substantiates this claim so far as mixtures are concerned. It found that of the National Health Insurance prescriptions for mixtures dispensed during July, 1947, 83.1% in England were based on national and B.P.C. formularies against only 3.5% in Scotland. In Scotland medical men are more inclined to use repeatedly what are virtually their own formulae, and there were 18.9% of such repeated prescriptions. Non-identical mixtures comprised 16.9% in England and 77.6% in Scotland. The corresponding figures for privately prescribed non-identical mixtures were 53.4% in England and 91.7% in Scotland. There was in fact a much less frequent use of formularies in the case of private prescribing, and a corresponding increase in non-identical formulae, than in the case of N.H.I. prescribing.

In the case of ointments, creams, and pastes those prescribed according to formulary were 93% in England, 95.8% in Wales, and 71.2% in Scotland; these according to non-identical formulae, 7% in England, 4.2% in Wales, and 17.9% in Scotland. In addition, 10.9% in Scotland were prescribed according to doctors' own formulae. The report points out that, as opposed to the practice in regard to mixtures, most formulary ointments are bought from wholesale houses in the form in which they are dispensed. There is no appreciable divergence of practice where tablets are concerned, for they also are bought wholesale. These three groups of medicaments comprise about 65% of the total prescriptions. Proprietary preparations account for another 5%, and the remaining 30% consists of miscellaneous articles such as glandular preparations, liniments, appliances, and so on.

Ingredients and Prescriptions

It was found that in Scotland the number of doses per mixture is, on the average, higher than in England and the volume of the mixture smaller. In England ten- or eight-ounce bottles, containing tablespoon doses, are most commonly prescribed, whereas in Scotland the standard is a six-ounce bottle containing dessertspoon doses. There is no evidence that there are more ingredients in a Scottish than in an English prescription; indeed the figures indicate that on an average there are fewer ingredients in a Scottish prescription for both mixtures and ointments.

Stock mixtures are more popular in England than in Wales or Scotland, the average number kept in the English pharmacies visited being 13.6, in the Welsh 2.3, and in the Scottish 2.6. Two mixtures almost universally kept in stock were compound acid mixture of bismuth with pepsin, B.P.C., and compound bismuth mixture with pepsin, B.P.C. Practically all stock mixtures used in England, apart from these two, are compounded on the premises by the pharmacist or his staff. Concentrated mixtures bought from wholesale houses are rarely used.

The Working Party, commenting on this difference of opinion about the desirability of using stock mixtures, points out that the Scottish attitude is that each prescription should be regarded as a thing apart, since it is prescribed for a particular patient. This involves more work and may lessen the monetary reward. The English pharmacist, on the other hand, would probably argue that there must be small errors in dispensing the individual prescription and that these are greatly reduced by dispensing from a stock mixture. He might add that he uses up the stock mixture in a day or two so that it does not become stale. He therefore saves his own and his customer's time.

REPORT ON DISPENSING

In 1947 the Minister of Health and the Secretary of State for Scotland set up a Working Party "to investigate the differences in the work of pharmacists in England and Scotland in the dispensing and supplying of medicines and appliances, with particular reference to the position likely to arise under the National Health Service." The Working Party also included Wales in its survey. Its composition was as follows: W. Penman, F.I.A. (Chairman); D. A. Bryan, M.P.S.; G. H. M. Graham, M.P.S.; A. A. Meldrum, M.P.S.; and J. Shields, M.P.S. Associated with it was a steering committee, of which Mr. Penman was the chairman, composed of officials of the Ministry of Health and of the Department of Health for Scotland, the Secretary of the National Pharmaceutical Union, and a representative of the Pharmaceutical Standing Committee (Scotland).

The Chairman decided how many and which pharmacies should be visited. The number selected was 300, of which 215 were in England, 25 in Wales, and 60 in Scotland. They

* The report will be published by H.M.S.O.

Quality of Pharmacies

The Working Party classified the 300 small pharmacies into "poor," "satisfactory," and "good." Only one or two of the "poor" could be described as "bad." The "good" were establishments "not necessarily large, but of a definitely high class."

In England there were 2.3% poor, 90.7% satisfactory, 7% good; in Wales 8.3% poor, 83.4% satisfactory, 8.3% good; in Scotland 5% poor, 78.3% satisfactory, 16.7% good. The report shows that the standard is high and that the Working Party held the unanimous opinion that no exception could be taken to the system in either England and Wales or Scotland, and adds that it would be a mistake to compel either section of opinion to work on the lines of the other.

Doctors and Pharmacists

In England about 80% of the doctors do their own dispensing for private patients, whereas in Scotland only about 12% do so. The Working Party comments that under the National Health Service Scottish pharmacists will not have any appreciable increase in the total volume of dispensing because of reduction in private dispensing, while English pharmacists will have considerably more dispensing.

The Working Party next investigated the variation between the three countries in the respective proportions of N.H.I. and private dispensing by pharmacists. It found that in England and Wales combined N.H.I. dispensing amounted to about 77% and private to 23%; in Scotland the figures were 35% and 65%.

Information was obtained on the ability of pharmacies to cope with the increased business likely under the National Health Service. The Working Party concludes that (a) in about 80 to 90% of cases in England and 65 to 75% in Scotland it will be necessary to enlarge the *dispensaries*, but (b) only in about 10 to 15% of cases in England and under 5% in Scotland will it be necessary to enlarge the *premises*. The expense of preparing for the National Health Service will therefore fall more heavily on English than on Scottish pharmacists. Wales is in a worse position than both. The Working Party concludes that in most cases extra staff will be required for the extra dispensing, but they need not consist entirely of qualified or trained dispensers.

Remuneration

The Working Party considers that "certain differences of practice" between the countries are established and likely to continue under the National Health Service. It therefore considered whether these differences justified the continuance of differences in remuneration. It indicates, however, that in general no differences in remuneration exist at present, and it has therefore devised a uniform tariff embodying the following features:

(1) Where the work involved is the same, the fee should be the same. If the work is more onerous or more responsible than other work, the fee should be larger for that work, wherever it is performed.

(2) A suitable uniform definition of what is an ingredient.

(3) A built-up basic price for small quantities of drugs, the same as, or similar in effect to, the present Scottish device.

(4) When a built-up basic price is impossible or unsuitable, a uniform percentage on the wholesale price, but not necessarily the same percentage for every class of dispensing.

(5) Treatment of refund of purchase tax on a uniform basis.

(6) Suitable arrangements for payment for containers.

(7) A uniform but elastic scale of dispensing fees. The dispensing fee should consist of a comparatively small constant or universal fee, to which should be added a further sum depending upon the number of doses in some cases, or the number of ingredients, or a combination of the number of ingredients and doses. In the case of ointments, a quantity factor would have to be introduced.

It concludes that a basic fee could be determined which could be applied to a very wide range of prescriptions, and that this could be adjusted for mixtures, ointments, tablets, capsules, etc. Certain pharmacies provide services such as special analytical work, special analyses, and the supply of surgical instruments and apparatus. The Working Party considers that for the National Health Service pharmacists should be remunerated for these services.

THE SEVENTH BRITISH PHARMACOPOEIA

MANY CHANGES

The General Medical Council is publishing the new *British Pharmacopoeia* with effect from Sept. 1, 1948, when this issue will supersede previous issues for all purposes. This volume of over 900 pages is the seventh of its series. The first "Book containing a list of medicines and compounds," to quote the Medical Act, appeared in 1864. A second was published in 1867, and an Addendum in 1874. The third appeared in 1885, and a further Addendum in 1890. The fourth was issued in 1898, and a Colonial and Indian Addendum in 1900. The fifth was brought out in 1914, and the longest interval—eighteen years—elapsed before the sixth was published in 1932. In 1933 the Pharmacopoeia Commission, which was charged with the preparation of the volume, was reconstituted; an Addendum was published in 1936, and the Commission proceeded to prepare a new *Pharmacopoeia* with a view to its publication in 1942, in accordance with the principle that ten years should be regarded as a reasonable interval between successive issues. It was also expected that the middle of each ten-year period would coincide with the revision of the *American Pharmacopoeia*. The war, however, delayed publication, but between 1940 and 1945 six further Addenda were brought out.

Pharmacopoeia Commission

The Pharmacopoeia Commission has had as its chairman Prof. J. A. Gunn, who succeeded the late Dr. A. P. Beddard in 1939. The other members were Mr. R. R. Bennett, Prof. H. Berry, Prof. O. L. V. S. de Wesselow, Prof. D. M. Dunlop, Sir Percival Hartley, Mr. B. F. Howard, Dr. D. Hunter, Prof. W. H. Linnell, and Mr. T. Tickle, with Dr. C. H. Hampshire as secretary. Prof. Gunn, Mr. Bennett, and Mr. Tickle were members of the Commission which prepared the 1932 volume. The Commission was assisted by 12 committees. The Clinical Committee had as its chairman Prof. de Wesselow, and among its members were Sir Ernest Rock Carling, Sir Francis Fraser, Sir A. M. H. Gray, Sir P. H. Manson-Bahr, Prof. J. A. Ryle, Sir C. P. Symonds, and Prof. L. J. Witts. Other committees were concerned with pharmacology, biological products, pharmacy and pharmacognosy, general and pharmaceutical chemistry, also with vitamins, ointment bases, nomenclature, and doses. Acknowledgment is made of valuable assistance and suggestions from medical and pharmaceutical authorities, including the Royal Colleges and Corporations, the Royal Society of Medicine, the British Medical Association, the Pharmaceutical Society, and other bodies in this country and in the Dominions and Colonies.

Newly Included Monographs

The number of monographs in the new *Pharmacopoeia*, each dealing with a separate preparation, is about 800, and there are 24 appendices describing the various tests, determinations, and assays. The number of articles and preparations which have been included in this *Pharmacopoeia* and do not appear in that of 1932 as amended by the Addenda and notices in the Official Gazette is 155. Among these are 57 injections, 18 tablets, 10 vaccines, and 9 sex hormones. The new injections include those of adrenaline, antimony and potassium tartrate, antimony and sodium tartrate, apomorphine hydrochloride, bismuth and sodium tartrate, caffeine and sodium benzoate, dextrose, digoxin, emetine hydrochloride, heparin, morphine and atropine, neoarsphenamine, hydnoctarpus oil, progesterone, sodium bicarbonate, sodium sulphadiazine, sulpharsphenamine, sodium sulphathiazole, and tryparsamide, among others.

Compressed tablets have been dealt with on the same lines as in the Addendum published in 1945. The new tablets include those of acetylsalicylic acid with phenacetin, digitalis, digoxin, ergot, methyltestosterone, methylthiouracil, and thiouracil. The vaccines added include those for acne, cholera, dysentery (Flexner), whooping-cough, and plague, a staphylococcal vaccine, and "vaccinum tuberculinum."

The number of substances in the hormone series has been increased, especially by the addition of six members of the group generally designated sex hormones. In this group several substances prepared synthetically and having physio-

ANAHÆMIN B.D.H.

in Neurological Complications of Pernicious Anæmia

The hæmopoietic factor as presented in Anahæmin B.D.H. is essential for the prevention of subacute combined degeneration of the cord. Other substances, such as folic acid, will produce an adequate hæmatological response but allow neurological degeneration to appear and to progress unchecked. Potent liver preparations are essential for the satisfactory treatment of pernicious anæmia.

Each batch of Anahæmin B.D.H. is clinically tested before issue.

Anahæmin

ORAL PENICILLIN THERAPY

Clinical studies show that 'Tabloid' brand Penicillin (buffered with sodium citrate), in doses of three to five times those given by parenteral routes, maintains equivalent or higher serum levels and produces a comparable therapeutic response. The increased dosage necessary by the oral route is more than offset by its greater convenience and by the saving in professional time and attention.

'Tabloid' brand Penicillin is issued in bottles of 20 at 14/- (subject to professional discount). Each product contains calcium penicillin 20,000 I.U. and sodium citrate, 0.5 gm. Literature is available on request. A desiccant is now included in each pack to protect the products from moisture.

Casualties in circumstances of this sort frequently call for ophthalmic surgery.

One of the most suitable anaesthetics in use for eye surgery is Soluble Thiopentone, given as a total anaesthetic by intravenous injection. The eyes remain fixed and after-sickness is negligible.

Soluble Thiopentone has other important advantages — ease of administration, ease of portability, quiet respiration, non-inflammability. It is usually given intravenously, but may be administered *per rectum* as a basal anaesthetic.

Soluble Thiopentone is a mixture of 100 parts by weight of the mono-sodium derivative of 5-ethyl-5-(1-methylbutyl)-thiobarbituric acid, and 6 parts by weight of exsiccated sodium carbonate.

logical actions similar to those of natural hormones are included. While the purity of most of these can be determined by chemical and physical tests, biological methods are necessary for the assay of others and appropriate methods are described.

Other newly introduced monographs are concerned with benzyl alcohol, brilliant green, calamine, calchicine, dicoumarol, emulsion of liquid paraffin, ergotamine tartrate, dry extract of hamamelidis, heparin, dry lemon peel, neostigmin bromide, picrotoxin, potassium chloride, saccharin, tri- and tetra-chlorethylene, thiouracil, and zinc peroxide. A few suppositories are new to the B.P.—namely, those of cocaine, of bismuth subgallate, of hamamelidis, and of the last-named with zinc oxide.

Since the prescribing of fresh infusions in medical practice has continued to decline, the principle of preparing infusions from concentrated preparations has received full recognition. The monographs in this section include those on infusions of orange peel, senna, clove, calumba, quassia, senega, and one or two others. The arrangement of formulae for ointments and creams has been extended by the inclusion of certain newer cases, the formulae being designed to provide bases of different types.

Penicillin and Its Preparations

The sections relating to penicillin and its preparations comply with the regulations made under the Therapeutic Substances Act, and are in accord with the state of knowledge at the time the *Pharmacopoeia* was completed. Although the existence of different penicillins was known, the International Conference on Penicillin, which was called in 1944 by the Permanent Commission on Biological Standards of the Health Organization of the League of Nations, recorded its opinion that as a temporary measure it was desirable and possible to adopt as an international standard a pure preparation of sodium salt of penicillin II (or G), and to define an international unit in terms thereof. Advances in knowledge continue to be made relating to the different kinds of penicillin, the conditions under which they are produced in culture, their biological properties, and the possibilities of their application in medicine. When reliable and practicable methods for the estimation of different penicillins are devised and reference standards for their assay are adopted by international agreement it may be expected that due recognition will be given to these advances.

Vitamins A, B, C, and D, with appropriate methods for assay, are included. Of the vitamin B complex the constituents aneurin hydrochloride, riboflavin, nicotinic acid, and nicotinamide are described. So far as possible these substances are controlled by chemical and physical tests, but biological assays are described where necessary.

Some new antitoxins and vaccines have been added, as has protamine zinc insulin. The methods of preparing tinctures follow the general principles of the last volume, but no new tinctures are introduced. The description of methods of preparing sterilized materials for parenteral injection has been revised and extended. The sterilization methods described are designed to cover the preparation of such materials on either a large or a small scale.

Deletions and Changes

As many as 145 monographs which appeared in the 1932 B.P., or its Addenda, have been deleted from the new *Pharmacopoeia*. These include in the first place 17 tinctures, among them those of asafetida, concentrated capsicum, cinchona, krameria, concentrated quassia, and quillaiae. The four plasters given in the 1932 edition also disappear—namely, those of belladonna, cantharidin, colophony, and lead. Other deletions are ammonium carbonate (now represented by ammonium bicarbonate), acetone, dilute hydrocyanic acid, dehydrated alcohol, amylocaine hydrochloride, cinchona, copaiba, iron and quinine citrate, glycerin of alum, guaiacol, effervescent sodium sulphate, strophanthin, and trinitrophenol.

The deletions, as has been stated, include all the fresh infusions, also a number of injections—iron, mercury, and sodium morrhuate, among others—and certain of the solutions, such as strong solution of ammonia, solution of arsenious and mercuric iodides, solution of irradiated ergosterol, solution of glyceryl trinitrate, simple solution of iodide, and blistering

liquid. Some oils disappear, including those of Siberian fur and of sandalwood; also pills of aloe and asafetida and of aloe and iron; certain of the syrups—ferrous iodide, ferrous phosphate with quinine and strychnine, and ferrous phosphate with strychnine—and tablets of hexamine and of sulphapyridine, with others. Three sera are deleted—the anti-dysenteric serum (Shiga) and the anti-pneumococcus I and II. Finally some crude drugs appear no more, such as buchu, copaiba, jalap, linseed, and lobelia.

A few changes in name are made. For example, scammony resin becomes resin of ipomoea, and g-strophanthin becomes ouabain. In a few articles and preparations there are certain changes in composition, and in still fewer cases changes in strength. The most important of these last is in the solution of hydrogen peroxide, which is now to contain officially 5 to 7% w/v of H₂O₂, instead of between 2.5 and 3.5% corresponding to about twenty times instead of about ten times its volume of available oxygen.

Tests and Descriptions

The requirements of this *Pharmacopoeia* have been made to correspond, wherever possible, with the provisions of the international agreement made in 1930 for the unification of the pharmacopoeial formulae for potent drugs. It has not, however, been considered advisable as a general principle to adopt the practice of weighing liquids as well as solids. With few exceptions, liquids are measured by volume and not by weight, a practice more convenient both to prescribers and to pharmacists.

The monographs are set out with great clarity and precision. The custom has been continued of giving at the head of each monograph the Latin title. The American example of using English titles has not been adopted. The title is followed by the customary abbreviation and by the English title, this last not necessarily a literal translation. One change may be noted. The statements under the heading of "Characters" in the case of substances of known and definite chemical composition were formerly intended to be "descriptive of such physical and sensory properties of the substance as might be of importance for the medical practitioner and dispenser." In future, however, these statements are to be considered as constituting an integral part of the official standard. One of the General Notices states—

All statements contained in the monographs, with the exception of chemical formulae given at the beginning of the monographs, constitute standards for the official substances. A chemical substance, crude drug, or preparation is not of pharmacopoeial quality unless it complies with all the requirements stated.

The arrangement of the monographs has been improved: graphic chemical formulae are provided, and the tests are set out under appropriate side-headings. In the case of a chemical substance there is first given the permissible but not obligatory method of preparation, followed by the percentage purity, the description, solubility, identification, various physical standards where these apply, the limit tests, and finally the assay. In the monographs describing crude drugs the first paragraph states the biological source, and the description is given where necessary under the headings "macroscopical" and "microscopical."

The doses mentioned in the *Pharmacopoeia* are not authoritatively enjoined as binding upon prescribers. They are intended simply for general guidance, and represent, unless otherwise stated, the average range of quantities which are generally regarded as suitable for adults when administered by mouth. The doses are expressed both in the metric system and in the imperial system, and attention is drawn to the fact that the relation between the metric and the imperial doses of a given preparation as set forth in the test is of only approximate equivalence.

For all processes, chemical or pharmaceutical, the metric system of weights and measures is employed. One alteration is the replacement of the abbreviation "mil." as a short designation for millilitre by the term "ml." Weights are given in milligrammes, contracted throughout to "mg.," or in grammes, contracted to "g.," in tests and formulae and to "G.," in doses.

The work is being published for the General Medical Council by Constable and Co., Ltd., but the price has still to be announced.

Correspondence

Gesture of Peace

SIR.—Mr. Bevan has made a gesture of peace. How are we to respond? At first he spoke rather as a dictator, somewhat offensively and insolently, and rightly we objected, claiming that in the interests of the public we must retain our freedom. Now Mr. Bevan has conceded the major point at issue. He has sacrificed in the national interest the point his party had repeatedly stated to be part of its programme. On our side should we not meet him by conceding minor points of difference that remain and trusting the Parliaments and Governments we elect to deal fairly and reasonably?—I am, etc.,

Bromstead, Surrey

HERBERT CAIGER.

Minimum Requirements

SIR.—We may all welcome the improved atmosphere consequent upon Mr. Bevan's gesture regarding the salary question, but many of us are still perturbed by other points which have not been satisfactorily settled. It is difficult to see how a simple plebiscite could possibly express the detailed views of the profession on those points still at issue. I venture to put my own views, held for some time, and which I feel are minimum requirements to satisfy our difficulties in agreeing to enter the Service.

(1) I have always opposed the insistence on the right of appeal to the courts against dismissal, since such action could be ruinously expensive in time, money, and reputation to the doctor concerned. Far preferable is the right of appeal to the Tribunal envisaged in the Act, provided that such a Tribunal were appointed by the Lord Chancellor and in no way by the employing authority.

(2) The retention of goodwill of practices is not a question of finance but has as its fundamental object the freedom of the profession. Unfortunately this issue has become a matter of emotion rather than good sense and the public and all political parties appear equally opposed to its retention. In view of this I feel that doctors might give up the goodwill of practices provided that the Act were amended to safeguard certain essential freedoms and to facilitate partnership and group practice arrangements.

(a) A doctor must have the right to select at his own discretion a partner, assistant, or locum tenens on terms mutually agreed.

(b) The payment of adequate compensation at the time for that proportion of a practice income transferred to an incoming partner.

(c) The payment of adequate compensation on death, retirement, or removal from one area to another.

(d) The removal from the Act of the power of negative direction, since the closing of certain areas to new entrants would nullify the freedoms envisaged in the foregoing clauses.

The points expressed in this letter could in no way diminish the objectives of the National Health Service Act but if conceded might well achieve the good will of the medical profession. Anything less than a whole-hearted co-operation by the doctors would be a disaster to the Health Service envisaged for the nation.—I am, etc.,

Trenton

R. D. ROWLANDS.

A Bad Service

SIR.—Once again the Presidents of the Royal Colleges, failing to learn from the unhappy results of their previous intervention, have superseded the Negotiating Committee in its dealings with the Minister. They have given to the public the erroneous impression that they are armed with a mandate from the whole profession. The positive result of this is that the Minister has scored the "face-saving" opening for which he has been waiting in order to make a concession to the doctors. He has given way on one principle only among those upon which we have been firm stand. The song and dance which has resulted in this has given points to the negative result of this second stab at the Act. If we continue to decline to work the Service we shall incur a bad press and incur the hostility of our patients.

In point of fact we are very little further advanced towards the achievement of our minimum standard than we were before. This remains a bad service from the point of view of the public. Even if we doctors agree to work it, where are the nurses, the hospital beds, the health centres? From the doctors' standpoint where are the secretaries and receptionists needed to replace our hard-worked wives, who rightly have no intention of acting as unpaid slaves for the Minister? In what way does our remuneration coincide with the recommendations of the Spens Committee? Will the Government pay us rent for the use of our surgery accommodation, having postponed indefinitely the building of the promised health centres? Why should we not retain the ownership of our practices? Take that away and our incentive to keenness and enthusiasm goes with it. These and several other points require a satisfactory answer before we should agree to enter the Service. Meanwhile, let us hope that the Presidents have not damaged our case irreparably with the public. Here, indeed, is an urgent job for the Public Relations Officer.

By all means let us have our service; but let it be one which the country in its present dire straits can afford. Let it be introduced a step at a time until we have the first-class service which we all desire. And meanwhile let our Negotiating Committee stand firm at the line upon which they received the mandate of the profession at the recent plebiscite.—I am, etc.,

East Horsley, Surrey.

BASIL S. GRANT.

Special Procedure

SIR.—From the general practice standpoint I should not be happy to see Regulations "vetted" by a Parliamentary Committee. We as a profession know far more about the N.H.S. Act than 20 Parliamentarians who are, or should be, interested in all the Acts they have framed. In addition to this we can realize at once the effect of a regulation on practice. The I.A.C. or its successor is the best body to "vet" new regulations as they affect general practice. A renewed assurance that regulations affecting general practice should be sent to the Association's Committee within whose terms of reference they naturally fall, and a similar assurance for consultants, would in my view meet the case without any further committees.—I am, etc.,

Solihull, Warwicks.

ARTHUR BEAUCHAMP.

Ownership of Goodwill

SIR.—Mr. Bevan's latest "concessions" are a clever move designed to split the profession. Actually he has given away very little, and there is nothing to prevent his introducing a Bill at any time to make the Service a whole-time salaried one in spite of all his assurances. To my mind, the ownership of our goodwill is the essential thing; if we lose that, we have nothing.

There are those among us who strongly believe that within ten years there will be so many of the public dissatisfied with the National Health Service that a considerable number of doctors will be leaving the Service to do private work only. I feel also that a great many doctors will be sadly disillusioned over their compensation when it comes to be worked out. Some members of our profession who have already had experience of Government contract service know how the doctors' work will be interfered with right, left, and centre by non-medical people.

Let us stick solidly by the B.M.A. no matter what the result of the plebiscite, and have faith in our patients and the public: we can trust them more than the politicians. United we stand, divided we fall. Don't let us ever forget that. There will be much work for the B.M.A. to do during the next few months no matter how the plebiscite goes, and we must have unity if we are to achieve anything of lasting value.—I am, etc.,

Burton-on-Trent.

J. R. SALMOND.

Cat-and-Mouse Game

SIR.—Whatever the outcome of the plebiscite now being conducted, I feel, and I am sure many feel as I do, that the action of the Council of the B.M.A. merits very severe condemnation.

Mr. Bevan had hardly regained his breath after his speech in the House of Commons on the National Health Service when the B.M.A. Council seemed to have developed hysteria and summoned an emergency meeting, and it was not long after that

their chosen spokesmen were waiting, cap in hand as it were, to see what tit-bits they could extract from the Minister. Why the hurry on their part? The Minister knew our terms and he was not prepared to yield and defiantly stated that the Health Service would start on the appointed day whatever our feelings. We as a profession had expressed in no uncertain terms our unwillingness to accept service under the Act as it then stood at the time of the last plebiscite, and the Council of the B.M.A. had undertaken to respect the vote of the profession. It therefore had no authority from the profession to meet the Minister and reopen the subject. By doing so the Council, in my opinion, has committed a serious breach of faith, and furthermore the profession has been held up to ridicule and our case has been weakened.

I am a staunch supporter, Sir, of all the principles for which the B.M.A. has been fighting, but at the same time I can recognize and condemn weakness; and it is not likely that I, or those who feel as I do, will be prepared to part with £100 for the privilege of standing outside the arena to watch this "cat-and-mouse" game. It's got to be all or nothing, and unless we adopt this attitude it is worthless making a mock attempt to fight for principles.

The eyes of the rest of the world are focused on us. Medicine throughout the universe will either sink or swim according to the strength of our efforts in this struggle. We try to pride ourselves on being the "guiding-star" in the field of medicine, but we cannot uphold this reputation unless we make a very determined and unflinching stand in the interests of a profession which throughout the ages has had the confidence of man. If we have not the courage to do this on our own behalf, let us do it on behalf of the man and woman who trust us to protect their lives and interests.—I am, etc.

London, W.1

E. S. FENNEL.

Unsolved Problems

SIR.—Ownership of the Family Doctor's Practice.—The Socialist Party have declared their determination to abolish the right of a doctor to own his practice and are determined to buy him out at great public expense. Their spokesmen have given three reasons for this, two of which are untrue, the third quite irrelevant. (1) "In no other country do doctors buy and sell the goodwill which they have built up in their practice." This is untrue. In many countries, including Belgium and Holland, the introduction to an accumulated practice is by purchase. (2) "Even the Conservative Party would not agree to the retention of the right to sell goodwill." The Conservative Party have never published any policy to this effect. Indeed, in a "property-owning Democracy" doctors should be encouraged to own their own practices. (3) "With doctors remunerated by public funds it would be unthinkable for a practice to be sold." This is quite irrelevant, as the patients would be accumulated as personal patients of the doctor.

What then is the system the Socialists have invented to replace the old pattern of natural supply and demand? It is this: that committee rule will prevail and doctors will be prevented from going into areas which are "over-doctored." This is a fantastic solution, as it cannot rectify the main difficulty which it is supposed to correct—i.e., that a few areas are in fact under-doctored.

Doctors cannot in any case go into adequately doctored areas and make a living without (1) buying a part or whole of a practice, or (2) securing a salary as an assistant, or (3) spending any capital they have at their command in building up a practice. No doctor would buy a practice in an under-doctored area, for there he would "squat" and build one up quickly. And how doctors in the new Service will be appointed to the best or least desirable practices no one knows. In this "paper" service the essential details are quite unworkable and unworkable.

The Doctor's House.—This is another unsolved problem. The outgoing doctor not being allowed to sell his practice, it is highly improbable that the incoming doctor will succeed to the house and surgery, for if he sold his house at the present market value to another doctor at a price deemed to include sale of goodwill he could be fined or imprisoned, or both, under Sect. 34, N.H.S. Act, 1946. Obviously a non-medical purchaser must be found and the house lost to medical practice. Where will

the incoming doctor get a house in these days of acute housing shortage?

Mr. Aneurin Bevan has thought that the doctors' "unease and restlessness" could be banished by some minor adjustment in the payments of basic salary and capitation fee. How little does he grasp the deep objection of the medical profession to being forced either into a State medical service or a whole-time State salaried service. Tradition and experience attach doctors to their patients. It will be increasingly difficult to be loyal to their patients with State interference at every level by daily increasing highly paid bureaucrats.—We are, etc.

G. H. ROSSDALE.

Events in Czechoslovakia

SIR.—I am sure we all feel saddened and disturbed about the turn of events in Czechoslovakia and their reflection in the boycott by the British of the centenary celebrations of the Charles University, but we do want our friends in that country, especially in Prague, to realize our real sentiments of good will and regard towards them. Possibly the *British Medical Journal* may be a means of communication that can take the place of so many avenues that are closed. Those of us who were to receive honorary degrees or to act as official representatives of universities or other learned bodies were bitterly disappointed to have to deny ourselves the privilege of attending as an act of homage to so ancient a seat of learning. To have done so would have been to condone the new stifling regime with its suppressions and frustrations. There is also another reason which I have not seen mentioned: to have been present and to have warmly recognized our friends would have been natural but might have brought suspicion or official disapproval upon them, while studied neglect on our part as a policy of safety might have been misunderstood and might have offended them deeply. In the dilemma it seemed best from all points of view to stay away, much as it was to be regretted.—I am, etc.

Taplow Bucks.

G. GREY TURNER.

Medical Photography

SIR.—Most workers in the laboratories and other ancillary departments of hospitals would agree that Dr. Ffrangcon Roberts (March 13, p. 485) has not in any way exaggerated the increasing demands on their services, nor minimized the relatively little contribution to the beneficial treatment of the patients which such demands have produced. I have recorded elsewhere (*Brit. J. Radiol.*, 1945, 18, 249) the main abuses of radiology, but apparently only inordinate boasting of his specialty by the expert (which will the more readily bring it into disrepute) can achieve any appreciable effect.

Though, as Dr. Roberts has shown, there has been a general increase in the demands for some years, since the end of the fighting of World War II, and more particularly since the Minister of Health announced his intention of taking over the hospitals, the full-time personnel and the expenditure of the larger hospitals, aided by their priorities, have increased considerably, but nothing to what they would have done had the services, goods, accommodation, and funds been more readily available.

With 42 years' experience in medical photography I do not share Dr. R. G. W. Ollerenshaw's views (March 27, p. 618) on it. "Doing it the hard way," as I could show, we were able to make as good illustrations 40 years ago as we can to-day, and I doubt very much whether the present facilities which permit of easier production will do any more than excite extravagant expenditure of material and time. True, much of the medical photography in the past was done at the expense of the interested clinician—a very useful corrective which I see no excuse in departing from.

Dr. Ollerenshaw admits that "it is quite certain that the demands of teachers for the products of the department are wellnigh overwhelming in spite of expansion," but is not this claim "for teaching purposes" being overdone? Have we not excellent illustrations in the literature of all the more common conditions? The rarities, though most interesting, are infinite, but of little use for teaching purposes. We have the optical facilities for projecting or reproducing any illustrations. He states that improvement in the standard of pictorial and line work submitted to the journals for publication is much needed. But surely in these days of high quality production this is a reflection on the efficiency of the editorial boards.

I find in present case histories, and indeed in the literature, illustrations which are not wanting in quality, but their legends and descriptions sometimes are lacking in accuracy, apparently because the condition illustrated is ill-understood. Included in a large number of cases in a series, illustrations of conditions are recorded which are not of the series, and often it is this erroneously included illustration which is chosen for resemblance by other writers adding to the series. Very few of the multitudinous photographs possessed by those who have shown enthusiasm for medical photography are put to any general use. Good as they are and interesting to the particular observer, he is given little chance of using them, and, as photographs are made to show the features the interested observer wishes, only he may appreciate their value and what they were made to show. It is said that the photograph cannot lie, but those who understand their possibilities, even with the cinema, know that a very false impression can be created, though it was neither designed nor wished.

How many of the teaching cinema films indicate to the student the difficulties of their productions, quite apart from the photography? The film may appear to indicate a skill, dexterity, or result far different from the actual. The very simplicity of a procedure in skilled hands may entice the novice to try his hand. With such education and practice the novice in sculpture would not be allowed to maltreat a piece of marble.

Medical photography results in the accumulation of material which can be of little material value. Like the snapshots of the amateur they become so numerous as time goes on that they fill every available space, and only removal or death secures their destruction. While writing this letter I have received a hospital report which records under this heading: "It is interesting to make comparison with previous years:

1945	..	1,119	negatives	4,506	prints
1946	..	3,360	"	6,996	"
1947	..	4,958	"	10,652	"

What a magnificent increase! For what?—I am, etc.,

Letchworth, Birmingham

JAMES F. BRAILSFORD.

Health of Students

SIR.—Dr. Emily A. C. Wilson (April 10, p. 708) was puzzled by the conclusion in my article (March 13, p. 490) on "The Health of 407 New Students" with regard to previous dental treatment: "It seems probable that financial considerations had prevented some of the students from the poorer social groups from obtaining dental treatment."

It would not be correct to assume, as I think Dr. Wilson does, that students entering a university in October, 1946, had all had free dental inspection and treatment offered them in their secondary schools. In the report of the Chief Medical Officer of the Ministry of Education for the year 1939-45¹ it is stated that "under the Education Act of 1921, relatively little was done to provide dental treatment for secondary school pupils." The Education Act of 1944, which was not implemented until April, 1945, obliges local authorities to provide dental treatment facilities for secondary school children, but owing to the call-up of school dental officers during the war, which in some areas amounted to half the dental staff, there are still secondary schools which have not yet been visited.

Mr. Sidney Pappworth (April 3, p. 663) finds it difficult to believe that 16% of the Sheffield freshmen had postural defects of the spine, yet Parnell² found an incidence of 28% in a group of Oxford students. In asking for controls he perhaps misunderstood the purpose of my survey, which was to describe the health of a group of university students with a view to discovering the health needs of this group. No attempt was made to show that their state of health differed from that of non-students of a similar age, and therefore no control series was necessary.

Dr. L. J. Kelleher (March 27, p. 617) objects to my psychiatric terminology. The term "marked introversion" conveys, I believe, to the ordinary medical reader the type of person meant, and "nervous breakdown" referred to a recent history of this condition, as the text of the article indicates. It would have been better, I think, for a non-psychiatrist to have attempted to translate this expression into an "accepted psychiatric syndrome." The students were not subjected to the Rorschach or other psychiatric tests. As Dr. Kelleher's article (March 13, p. 504) states, special mental tests have been tried in one university in the United Kingdom, but were discontinued as it was found that they failed to justify the additional organization, work, and expense. The placing in charge of a student health scheme certainly is not the province of a psychiatrist in the diagnosis and treatment of mental ill-health, which, as you state,

are not rare. He also needs the help of an orthopaedic surgeon, oto-rhino-laryngologist, dermatologist, and other specialists for the treatment of established illness in students. In the University of Sheffield students' health service we have been fortunate in receiving much valued help of this kind from the consultant staffs of the Royal Sheffield Infirmary and Hospital.

Those who have not themselves had the opportunity of carrying out routine health examinations on unselected population groups are often surprised at the high incidence of defects and disorders reported in surveys of this sort. Morris,³ for example, examined 1,592 workers in a Midlands corporation and found that 7% had a major disorder, and that minor disorders such as "bad teeth, dyspepsia, hernia, chronic bronchitis, defects of hearing and vision, anaemia, varicose veins, and deformed feet were legion." Pearse and Crocker⁴ found that of the members of the Peckham Health Centre only 4% of the women and 14% of the men could be classed as free from disorder. Parnell's findings in examining a group of university students included 33% with myopia, 32% with skin lesions, 15% with ear, nose, and throat conditions, and 13% with minor anxieties. At routine health examinations illnesses such as hypochromic anaemia and pulmonary tuberculosis can be detected at an early and usually curable stage. At the same time deviations from the average, such as symptomless flat foot or transient systolic hypertension, are discovered, the significance of which is not yet fully understood. By following up individuals showing deviations of this sort it should be possible to determine which signs can be regarded as normal variations and which constitute the earliest evidence of disabling illness such as essential hypertension, peptic ulcer, and neurotic or psychotic breakdown. Possibilities in the prevention of the development of these illnesses might then emerge.—I am, etc.,

University of Sheffield.

Disk Lesions and Osteopathy

SIR.—Dr. James Cyriax (April 17, p. 754) has completely missed the point of my letter in reply to Dr. Craig and Mr. Lipmann-Kessel's letter. It was not my intention to draw an analogy between the osteopathic theory and protrusion of an intervertebral disk. Quite the contrary.

In order to make my point clear let me quote more extensively from Dr. Craig and Mr. Lipmann-Kessel's letter. They said, "It is generally accepted that on clinical evidence alone the level of a lumbar spine disk lesion cannot be confidently predicted. It may be that the present conception of sciatic pain as the result of root compression is responsible for this difficulty, and if it were regarded as a deep segmental pain due to joint disturbance this difficulty might be resolved. Over-simplified views of the pain mechanism in this condition are liable to follow a mechanical interpretation of the functions of the central nervous system."

While not denying that gross protrusion of an intervertebral disk accounts for a small proportion of cases of sciatica this broad conception of the probable underlying pathology not only of the majority of cases of sciatica but of many other conditions as well is exactly what has been suggested by the osteopaths for many years now. I repeat, in my opinion there is more truth in the osteopathic conception that has hitherto been admitted by the orthodox medical profession.

Many of Andrew Taylor Still's contentions have and will continue to be modified in the light of progressive knowledge but this in no way detracts from his great contribution to medical progress. Certainly the modern conception of circulation differs considerably from that enunciated by Harvey, but he is nevertheless universally acclaimed the discoverer of the circulation of the blood.—I am, etc.,

London, W.1.

GEORGE MACDONALD.

Intra-abdominal and Intrauterine Pressures

SIR.—In his interesting dissertation on the mechanics of egg laying (March 27, p. 585) Prof. H. A. Harris accepts the calculation by Houghton¹ of the maximum human intrauterine pressure during parturition. This reverend scientist was not, however, always near the mark with his calculations, as is shown by his figure for the maximum intra-abdominal pressure. From

measurements of the thickness of the muscles in the abdominal wall, the curvature of the linea alba, and the absolute muscle force, or maximum force per unit of cross section of the fibres, he arrived at the impressively exact figure of 32.926 lb. per sq. in. (1702 mm. Hg). The figure for the absolute muscle force which he used was 102.55 lb. per sq. in. (7.21 kg. sq. cm.), and this is nearly double my own figure,² which took into consideration many more factors.

Allowing for this discrepancy, however, Haughton's figure for the intra-abdominal pressure would still be many times greater than the systolic blood pressure. If this were actually the case the blood flow in the lower limbs would cease completely during periods of high abdominal tension. But a simple observation that the pulses at the ankles are still present during severe abdominal straining indicates that the intra-abdominal pressure must be less than the systolic pressure. This is confirmed by measurements which I made some years ago by introducing a balloon, connected to a manometer, through the opened sac of an inguinal hernia exposed under local anaesthesia, and then with a swab pressed firmly over the inguinal canal encouraging the patient to strain down with maximum effort. The best two readings in six cases were 75 and 80 mm. of Hg, and there was no doubt that these young men were trying hard. Barcroft and Mullen³ have shown that the tension within a voluntary muscle at maximum effort can be high enough to stop its blood flow, but from the above readings it is apparent that the maximum intra-abdominal pressure is well below the normal systolic level.

It seems likely that this applies also to the maximum intra-uterine pressure, since a pressure greater than systolic levels would cut off the flow of maternal blood through the placenta and would arrest the foetal circulation. The figure of 3.4 lb. per sq. in. arrived at in Haughton's calculations is therefore likely to be well above the actual maximum pressure. His work illustrates well the fallacies which may result from inductive reasoning applied to body functions—the only way to get at the truth is to “try the experiment”—I am, etc.

Prompt Publication

SIR,—I have always had the greatest admiration for the department of the B.M.A. which is responsible for the publication of the specialist quarterly journals, but recently this department has quite excelled itself. In the issue of the *Journal of Neurology, Neurosurgery, and Psychiatry* dated November, 1947, there appears a long and valuable article which was received at the editorial office on Nov. 29, 1947. Such an achievement demands and must receive the warmest congratulations. As the journal cannot be expected merely to rest on its laurels in the future and must like all of us “raise its sights” I suppose that we can confidently look forward to the time when it will be publishing articles some months before they are written.—I am, etc.

SAMSON WRIGHT.

The Problem of Caries

SIR,—Your annotation (April 10, p. 697) on this subject requires some clarification and correction. Does the writer maintain that caries does not, or that it need not, involve decalcification, or merely that it is not purely and simply decalcification? Or does he mean that proteolysis may or does precede decalcification either in enamel or dentine? What conception is it that recent work has shown to be untrue, and what decalcification hypothesis is it that Dr. P. Pincus has “shattered” with his earlier work?

The chemico-parasitic theory was not originally deduced from a “belief,” but from observation of now well-known facts, and it has since been amply confirmed by nearly all the work that has been done on the aetiology and prevention of caries. Frisbie's theory, which you refer to, depends on his observation¹ that some alteration of enamel occurs while its natural surface, and the surface of ground sections, is still “essentially hard in the physical sense.” Examination by means of instru-

ments may or may not reveal a roughened or irregular surface.” This vaguely described observation seems to be his only reason for supposing that no decalcification had occurred. However, Applebaum² has shown that carious enamel becomes radiolucent to Grenz rays before its surface continuity is lost and while it is still hard enough for the preparation of ground sections. This clearly indicates that decalcification has begun at that very early stage.

The earlier paper of Pincus,³ which is cited, does not specifically describe any destruction of the hard part of the enamel but merely some alteration in the surface of teeth which seem from the illustrations to be still covered with Nasmyth's membrane or the remnant of the enamel organ. It is not stated how long the teeth had been erupted or whether they had erupted at all. No sections are described or illustrated, and the author only claims that the appearance suggests that “some of the enamel was disintegrated.” Few would agree with him, unless by “some of the enamel” he means only the organic matter lying on or at the surface of newly erupted or unerupted enamel. He makes no claim to have shattered any hypothesis, and the real value of his work as dental research is, I suggest, that after years of painstaking effort he has not been able to produce anything resembling caries in the absence of acid or acidogenic bacteria. Artificial or *in vitro* caries with acid-forming bacteria has of course been known for many years.

Perhaps the writer of the annotation was misled by the statement of Dr. Pincus, in his discussion of caries, that dentine is 25% organic matter. Enamel, where caries usually begins, has a much lower content—usually reckoned as about 2%. It has long been realized that proteolysis is an essential part of dentine caries, but there is still nothing to suggest that it is essential or important in the caries of enamel.

A glance at any number of the *Journal of Dental Research* will show that the theories of Pincus and Frisbie are not as your annotator suggests widely accepted by research workers in the U.S.A., and his own views go even beyond the unorthodox theories of those two workers. The last paragraph of the annotation is also very puzzling. Why does caries occur at stagnation areas if stagnation areas are caused by caries? Surely it would be better if comment in the *Journal* on Pincus's theory was made from a more orthodox or impartial viewpoint, or at least that such extreme and obscure theories should not be presented as though they were generally accepted?—I am, etc.

- ² *Dental Cosmos*, 1935, 77, 931.
- ³ *Brit. dent. J.*, 1937, 63, 511.

SIR,—I read with interest and some surprise in the annotation (April 10, p. 697) on this subject that “many dental research workers still refer to dental caries as a process of decalcification”; that “recent work . . . indicates that this conception is far from the truth”; and that “it is on such lines that much of the research work on caries is now being done in the U.S.A.”

I have just returned from a five-and-a-half-months tour of research centres in New York, Ann Arbor, Mich., Rochester, N.Y., Minneapolis, Indianapolis, and others, for the express purpose of discovering the views of the research workers upon dental caries and its prevention. My impression is that the conclusions of the overwhelming majority of these men are diametrically opposed to the views expressed in your annotation, and that notwithstanding much research upon proteolysis.

I quote the findings of that large body of research workers known as the “Michigan Workshop,” whose 25th meeting was held from Sept. 8–13, 1947, as published in the *Journal of the American Dental Association* (1948, 36, 4): “Dental caries is a disease of the calcified tissues of the teeth. It is caused by acid resulting from the action of micro-organisms on carbohydrates, is characterized by a decalcification of the inorganic portions, and is accompanied or followed by a disintegration of the organic substance of the tooth.”

Fosdick, Professor of Chemistry at the North Western University, states in the *New York Journal of Dentistry* (1947, 17, 55), “Recent research in dental caries has primarily emphasized the early position of Miller and Black, in that the condition is an acid decalcification of the inorganic structure of the teeth accompanied or followed by a putrefaction of the organic portions.”

Volker, in the *Journal of the New Jersey State Dental Society* (September, 1947), says, “In conclusion it may be reiterated that our present knowledge of dental caries supports the view that we are

dealing with an environmental process in which three factors, retained fermentable carbohydrates, acidogenic bacteria, and the enamel surface play the leading roles."

It is true that certain writers, notably Prof. Gottlieb, believe that proteolysis is of major importance in the initiation of dental caries, but it is my experience that these men find few sympathizers among the research workers in the U.S.A.

Dr. Pincus's interesting and valuable contribution in your same issue throws further light on the role of proteolysis in the progressive increase of a cavity when once formed. As one interested in the prevention of dental disease, the question as to whether the primary breach in the enamel of the tooth is due to proteolytic or acid-forming organisms is of far more than academic interest.—I am, etc.,

London, S.E.1.

GILBERT J. PARFITT.

Aluminium Pneumoconiosis

SIR.—In the annotation (March 13, p. 506) you have a comment on aluminium pneumoconiosis. This write-up is very interesting. I would like, however, to correct a rather doubtful statement made therein. The article states, "The Canadian investigators think that the disease may be a form of silicosis caused by vaporized silica." Just what your authority for this statement is, is difficult to see. We have always been conscious that, in the presence of so much silica, silica as a possible cause or contributing cause of the condition found in the abrasive workers could not be overlooked. We do not, however, feel that this is modified silicosis. We incline to the opinion that the disease is produced by the extremely heavy exposure to alumina. It is realized that as yet we have not complete evidence that this opinion is correct. Some experimental work is being done which may resolve the problem.

It would be interesting if you canvass the situation in regard to an aluminium plant in Sweden. Dr. Sven Forssman, Professor of Industrial Hygiene, State Institute of Public Health, Tomtebodavägen (near Stockholm), Sweden, showed me two lantern slides from films prepared on men who had been employed in the plant concerned. The lung changes exhibited by these slides were very similar to those found in our abrasive workers.—I am, etc.,

Director of Industrial Health,
Department of Health,
Toronto, Ontario.

A. R. RIDDELL.

Medicine and the Arts

SIR, Prof Geoffrey Jefferson is too sweeping. In the course of a reply (April 10, p. 705) to a scientific correspondent he makes a brief excursion into the arts, and in half-a-dozen lines disposes of Elizabethan prose and the writers of long poems. He writes, "The art of tight and lucid compression of thinking was unknown in Bacon's day." Surely Bacon, on the contrary, was the earliest English exponent of the aphorism, the essence of which is conciseness. In his *Advancement of Learning* he distinguishes two methods of writing, by formal discourse or by aphorism. One method or the other was to be adopted—they could hardly be combined—and therefore he practised both. The difficulty of reconciling comprehensiveness with brevity is an old one.

From prose to poetry, and the professor's faith in Baudelaire's dictum, "Long poems were written by those who had not the talent to compose short ones." This can hardly be dismissed with a smile as an exaggeration, because it is not the exaggeration of a truth. Rather is it a Gallic *bon mot*, not to be taken too literally; perhaps Baudelaire was a better poet than critic. Be that as it may, the English Muse refutes him wherever the pages are turned, even in Lancashire. One example will serve to counter Baudelaire's thrust and display a master's mastery of both forms, the long and the short—that is, a short poem "The Poppy" with its opening stanza,

"Summer set lin to Earth's besom bare,
And left the flush'd print in a poppy there;
Like a vawn of fire from the grass it came,
And the fanning wind puff'd it to flapping flame."

The poet is Francis Thompson, one-time student of the Manchester Medical School (1877-83), who was capable, too, of a master's mastery in his long poem, "The Hound of Heaven"—I am, etc.,

F. G. RALPHS.

Bone Conduction in Otosclerosis

SIR.—It is interesting to note the contradictory opinions expressed by the commentators on my letter printed in the *Journal* of March 20 (p. 569). Mr. R. Scott Stevenson (March 27, p. 618), quoting the work of Tumarkin, refers to "the myth of increased bone conduction" in otosclerosis. Mr. R. R. Woods (April 17, p. 754), while referring to the genuine improvement of bone conduction which occurs in the operated ear (after the fenestration operation), goes on to say that he has never seen the hearing of the unoperated ear altered in any way, either for air or bone conduction; indeed, he says it is inconceivable that an operation on one ear could affect the working of the opposite one. Mr. E. R. Garnett Passe (April 17, p. 754) writes, "It has been known for some time now that improvement to hearing by both air and bone conduction occurs in the unoperated ear in a certain number of cases, but this improvement is never permanent."

The case I referred to illustrated the fact that increase in air and bone conduction can occur in the unoperated ear, and I made no claim whatsoever to a permanent result for this case. In February, 1947, Mr. Passe published in the *Lancet* the results of one hundred fenestration operations done by the Lempert technique since August, 1945. With an equal operative experience to this number over the last two years, and with an operative technique which the results substantiate, I hope I can give equally well what he and Mr. Scott Stevenson call a "careful, sober, and dispassionate estimation of end-results."—I am, etc.,

London, W.1.

W. H. B. MAGAURAN.

Transfusion Reactions

SIR.—Dr. John Wallace and Mr. R. D. Richards in their article (April 3, p. 640) on transfusion reactions describe cases in which venous spasm interfered with infusion of red cells. I have seen a reaction to infusion closely resembling the case described in detail in the article, where venous spasm also seemed to be the cause. Other evidence, however, suggests a different explanation. The recipient was a healthy nurse belonging to Group A. She was given 500 ml. of Group O blood in order to estimate survival of the donor's red cells in a normal person. Venipuncture was performed apparently satisfactorily, and the infusion ran quite freely. Some thirty minutes after the transfusion began the recipient complained of a little aching in the arm, and when nearly 400 ml. had run in the pain became more severe. It was now noticed that there was acute tenderness and swelling localized to the biceps. The infusion, however, was still running quite freely, but was stopped in view of the discomfort.

In estimating the survival of the Group O blood, using the method described by Ashby in 1919, as modified by Dacie and Mollison in 1943, it was found that no increase in the number of inagglutinable cells (Group O cells) had occurred after the transfusion was stopped. From this it was inferred that none of the infused cells had reached the general circulation. Swelling of the biceps was followed by discoloration of the skin of the lower arm and upper forearm. Full recovery of function in the arm and subsidence of the swelling took place in about ten days.

From these observations it seems likely that the blood was infused into the intramuscular spaces in the biceps due to the intravenous needle passing through the vein into the muscle, and that venous spasm was not the true explanation of the reaction.—I am, etc.,

Manchester.

W. K. STEVENSON MOORE.

A Case of White Asphyxia

SIR.—It is still no exaggeration to say that many theatres in the country are not equipped for this emergency and, what is more, there is much scepticism regarding the efficacy of cardiac massage. Various claims have been made as to the period of cardiac arrest from which recovery has taken place, but the average time limit is five minutes. The central nervous system can tolerate total arrest for three minutes ten seconds, and, even then there is some permanent alteration in psychic behaviour.

On Dec. 18, 1944, a man aged 68 underwent partial cystectomy under light spinal "nupercaine" and light general anaesthesia. While the abdominal wound was being closed the anaesthetist reported that the patient had stopped breathing. On examination his was a typical case of white asphyxia. By the time cardiac massage was started through an upper abdominal incision three to four minutes must have elapsed. He was given nikethamide, and artificial respiration was commenced at the same time. Cardiac massage had been carried out for about two minutes when the heart started beating again. Some adrenaline was injected into the heart muscle. The patient was returned to the ward, and by slow drip one pint (568 ml.) of blood was given, along with an intramuscular injection of suprarenal cortex extract. The patient was still in deep coma at 9 p.m. The night nurse reported: "Patient seems to be semi-conscious, but is very dazed." In the morning to my great surprise he was semi-conscious and irrational. He was restless for a few days, and from Jan. 1, 1945, his condition improved. On Jan. 3 he was fully conscious, but on the 4th he again became restless, and was not able to pass urine. Two stitches were removed from the suprapubic wound and a large blood clot taken away. Next day, as he did not improve, the suprapubic wound was reopened under local analgesia and intravenous "pentothal," a blood clot removed, the bladder washed out, and a suprapubic drain put in. Progress was satisfactory until Jan. 12, when the upper abdominal wound burst open, with protrusion of omentum. Under local and regional analgesia the abdominal wall was resutured. Progress was uneventful, and he was discharged fit, passing urine normally. He was sent to see Dr. F. M. R. Walsh and Dr. Parkinson. Both reported no organic changes as a result of the asphyxia. When last seen he was fit and active.

The unusual features of this case are that the patient was able to stand two further surgical manipulations under pentothal and local analgesia so soon after his recovery. Though I have seen further examples of cardiac arrest which have not turned out so favourably I have become a firm believer in this life-saving measure. My own view is that for the measure to be more uniformly successful one must start the massage as promptly as feasible and in perfect confidence.

I wish to thank Mr. Harold Dodd for permission to publish this case.—I am, etc.,

Swames General and Eye Hospital

SUNDRAM PILLAI.

POINTS FROM LETTERS

Prickly Heat

Colonel T. C. RUSSELL ARCHER, late R.A.M.C., writes: Correspondence on the treatment of prickly heat has prompted me to forward the undermentioned formula for my colleagues in tropical practice: Salicylic acid, 3 parts; perchloride of mercury, 0.1 part; industrial methylated spirit to 100 parts. This formula was used by me with considerable success when serving with the West African Expeditionary Force in the Far East, but on reflection I feel it would be much improved by the addition of 70% alcohol in place of methylated spirits.

The Design of Bed-pans

"Professional Victim" writes: Having recently undergone a major operation I was much interested in Mr. Malcolm Donaldson's letter (March 27, p. 618) on the above subject. A doctor who had been wounded wrote to the *British Medical Journal* about it during the war. He pointed out that the bed-pan hinders defaecation by pressing the buttocks together. The lavatory seat, on the other hand, helps it by separating them and putting the anus on the stretch. . . . A bed-pan of a shape approximating to the lavatory seat might be clumsy for the nurses, but I believe it would reduce the discomfort of our patients enough to be worth the extra trouble involved.

Herpes Zoster and Chicken-pox

Dr. ERNEST SOYSA (Colombo, Ceylon) writes: The following cases may be of interest in reference to Dr. C. C. H. Chavasse's observations (Feb. 14, p. 318) on the association of herpes zoster and chicken-pox. On Jan. 19, 1949, a mother aged 40 took her daughter aged 13 to a doctor in whose household there had been several cases of chicken-pox during the preceding three months. On Jan. 28 the mother complained of pain in the right eye and supra-orbital region. The next day a few small vesicles appeared above the right eyebrow. By Feb. 1 a severe herpetic rash had spread over the right supra-orbital region, with acute frontal neuralgia, swelling, itching, laceration, and vomiting. The condition began to improve after a week. The pain subsided gradually, and the herpes cleared up leaving severe scarring of the right side of the forehead. On Feb. 14

the patient's daughter developed an attack of chicken-pox which was mild and subsided within ten days, leaving little scarring. On March 1 a maidservant who had looked after the last two patients also fell ill with chicken-pox and made an uneventful recovery.

Clothing Coupons for Colostomy

Mr. J. C. GOLIGHER (London, W.1) writes: It is not perhaps generally appreciated in the medical profession that additional clothing coupons may be claimed by patients with colostomies or ileostomies in order to cover the purchase of a suitable belt and the extra underwear, bed linen, etc., made necessary by their condition. . . . Patients should write to the Board of Trade (Invalid and Medical Section), 91, Victoria Street, S.W.1, and ask for Form P.C.128, on which the application should be made. A supporting medical certificate from the doctor or surgeon is also necessary. In completing the form it is important to state that the application is made in respect of both an appliance and extra clothing, otherwise only three coupons, just sufficient to buy a belt, will be sent. If the need for additional clothing is also mentioned, the allowance granted is 30 coupons. This is, of course, a yearly allocation and a fresh application should be made annually.

Sweet Urine Containers

Dr. P. E. FITZPATRICK (Belfast) writes: Dr. W. E. McCulloch's point (March 27, p. 610) interested me greatly, for it shows how a doctor can be completely taken in. About a year ago I had a patient who had been complaining of various nervous symptoms—paraesthesia, polyuria, etc.—and on clinical examination I could find no signs of any organic disease. As is my custom I asked for a specimen of morning urine, and I was extremely surprised to find it was full of glucose. Accordingly I referred my patient to a specialist for a blood-sugar estimation, etc., and imagine my surprise when I was informed that the blood sugar was normal and the urine was free from sugar. I did a further test and this time the urine was sugar-free. Accordingly I made a successful search for the bottle which contained the original sample (three days later), and examined it again. It showed glucose — + + —. Fortunately the label of the chemist was on the bottle with the code marking. I inquired of the chemist what had been in the bottle and he was able to inform me "glycerine and honey." Fortunately I had not informed my patient about the glycosuria, and she is now completely well, with no symptoms. The moral, I think, is obvious.

Asthma and the Inhaler

Dr. DENIS DOOLEY (London, W.C.2) writes: May I endorse the remarks of Dr. A. W. Pater-on (March 20, p. 573)? For a long time I have prescribed a bronchodylone type of inhalant for patients with asthma and am highly satisfied with the results. I suggest that the damage to the cilia as mentioned by Dr. Clement Francis (Jan. 10, p. 76) is caused by the acid in some of these inhalants. The preparation I prescribe is practically neutral, and the results in some cases are quite remarkable. . . .

p-Aminobenzoic Acid for Prurigo

Dr. DAVID S. CLARK (Yeovil, Som.) writes: I feel that the following case might be of some interest. I have a patient, a male aged 40, who has suffered every summer for the last eight or ten years from a form of prurigo aestivalis that has manifested itself as an itchy maculo-papular rash on any part of his body that has been exposed to the summer sun. The size and persistence of the spots vary with the intensity and length of the exposure, but half an hour's insolation has always been enough to produce the rash. By protecting the affected part from further sunlight and the use of local soothing remedies the rash has usually cleared in two or three weeks. On my advice he has been in the habit of avoiding sunlight as completely as possible, but at Easter this year his hands were exposed to the sun for over an hour. This provoked the usual rash. On this occasion I gave him no local treatment, but as a trial prescribed 200 mg. of p-aminobenzoic acid daily. For the first time in his memory the rash cleared within 48 hours. He has been taking this preparation regularly since and is now able to spend considerable periods in direct sunlight without suffering any ill effects.

Ante-partum Haemorrhage

Dr. TIM BOLAND (Sheffield) writes: In your report (April 17, p. 748) of the Edinburgh Obstetrical Society's meeting, Dr. R. de Soldenhoff advocated "the vaginal pack for certain emergency cases of ante-partum haemorrhage." Surely all obstetricians of repute are by now agreed that the vaginal pack has no place in the treatment of cases of ante-partum haemorrhage, whether emergencies or not. Any attempt to revive this shock-causing and septic procedure must be condemned.

Obituary

THE TRAGEDY OF MOUNT SCOPUS

We record with deep regret the deaths on April 13 of Dr. Doljansky, director of cancer research in the Hebrew University, Jerusalem; Dr. Yassky, director of the Hadassah medical service and deputy administrator of the cancer research department; Dr. Dostrovsky, physician at the University Hospital; Prof. Bonaventura, director of the psychology department; Dr. Ben-David, secretary of the medical faculty; and Mr. Cassuto, assistant in the department of bacteriology. They were killed in an Arab attack on a convoy of the university staff, including doctors, nurses, and patients, travelling from the city of Jerusalem to Mount Scopus. Dr. Freiman, lecturer in Jewish law, Dr. Klar, lecturer in philology, and others in the convoy were also killed.

Prof. Enzo Joseph Bonaventura was born in 1891 at Pisa. He attended the University of Florence, took his doctorate in philosophy there, and then studied experimental psychology. In 1915 he was appointed assistant in the Institute of Psychology, and from 1923 to 1938 was professor of psychology. From 1924 to 1938 he was also professor of child psychology. In 1939 he was appointed professor of psychology at the Hebrew University, Jerusalem.

Dr. Leonid Doljansky was born at Ekaterinoslav, Russia, in 1898. He took his doctorate of medicine at Berlin University in 1925 and then did research at the Kaiser-Wilhelm Institute for Biology until 1928. From then until 1931 he conducted the Laboratory for Experimental Cytology at the Pasteur Institute, Paris. He then returned to Berlin University as an assistant in the Institute of Pathology. From 1933 until 1935 he carried out research at the Carlsberg Fondets Biologiske Institut at Copenhagen. In 1935 he was appointed head of the department of experimental pathology in the cancer research laboratories at the Hebrew University.

Dr. Arven Dostrovsky was born in 1887 at Cairo, in Russia, and attended the Universities of Vienna and Basle, taking his doctorate of medicine at Basle in 1915. He spent a year as house physician at Basle University Children's Hospital and then went to Petrograd, as it was then called, to study skin and venereal diseases. From 1917 to 1918 he served as assistant at the skin hospitals of Dvinsk and Minsk, and from 1918 to 1920 as voluntary assistant at the Glavze Institute for skin and venereal diseases at Odessa. In 1920 he was appointed head of the department of skin and venereal diseases at the Rothschild Hadassah Hospital at Jerusalem, and in 1938 lecturer in dermatology and venerology in the Hebrew University.

Prof. Simon Wright contributes the following note: The Hebrew University and the University-Hadassah Hospital have suffered a grave blow as a result of many members of their staff having been killed by Arabs while going up in convoy to their place of work. I was invited two years ago by the University to go to Jerusalem to advise on the plans for the establishment of an undergraduate school of medicine. The University Hospital was completed just before the outbreak of war and is a fine, well-equipped building of some 400 beds doing first-class work. The Ratnoff Building alongside it houses the research and routine departments serving the hospital, such as those for pathology, biochemistry, hormone, and cancer research. Full facilities were thus available for the clinical part of the course. A good deal of postgraduate instruction in clinical and laboratory subjects was given during the war, and many R.A.M.C. officers enjoyed the facilities provided by the University for them. To complete the undergraduate school it was necessary to expand the existing departments of anatomy, chemistry, and biology, and to build new institutes for physiology, pharmacology, and pharmacology. In addition the department of instruction and examination had to be established.

During my stay in Jerusalem I came into intimate contact with many of the members of the staff, so many of whom were of Jewish origin. I had been the head of the Hadassah Hospital in Palestine and had been responsible for building up in the country a network of hospitals,

clinics, and specialist services of all kinds, which served faithfully not only the Jewish community but many Arabs also. Yassky had been the driving force responsible for building the Jerusalem Hospital, and he was chairman of the planning committee which was dealing with the medical school extensions. He was a man of great vigour of mind and body, and had an imagination restrained only by a keen sense of the practical. He is quite irreplaceable, for there is no one in Jerusalem with as complete a command as he had of the problems and their solution. The Biological Institute was started recently under his direction, and the building operations had continued in spite of the disturbances.

Dr. Ben-David, the secretary of the medical school, was a scholarly, patient, wise, and conscientious administrator who had made a special study of the problems of medical education and was particularly impressed with the Goodenough Report. He had to get agreement from a staff who had come from many lands and had brought with them their own university tradition, which each naturally wished the Hebrew University to follow. I had been in constant touch with him since my visit. His personality and knowledge will be sadly missed.

Dr. Doljansky was a first-class investigator in the field of cancer research and tissue culture. He belonged to the sensitive, artistic class of investigators. His laboratory was beautifully designed and arranged and appealed to the eye as well as to the mind. His technical skill was outstanding. His contributions to knowledge were numerous and distinguished. He had latterly acted as Dean of the Prefecture of Medicine. With the death of Yassky, Ben-David, and Doljansky the medical school has simultaneously lost almost the whole of its leadership. I fear that the opening of the medical school to students, which had been planned for October of this year, will inevitably be delayed. No one knows what new disasters may yet befall Jerusalem in the coming months, but all friends of the Hebrew University will pray that it will survive to carry on its beneficent work for science and learning.

G. T. CALTHROP, M.D., D.M.R.E.

Dr. G. T. Calthrop died at his home at Luffenhall, near Stevenage, on April 14, at the age of 57. Gordon Thomas Calthrop was educated at Trent and Emmanuel College, Cambridge, graduating B.A. with honours in 1915. From there he went to the London Hospital, where he took the conjoint qualification in 1918, and the Cambridge M.B., B.Ch. the following year. After serving as house-physician at the London Hospital and as resident medical officer at the City of London Chest Hospital, during which time he took his D.P.H., Calthrop entered the service of the P. & O. as ship surgeon. His choice of a career was largely influenced by his physical disability, the result of a rheumatic carditis. It was at this time that Calthrop first became interested in radiology. He installed in his ship at his own expense a portable radiographic outfit. Possessed of a keen intellect, he found that his life at sea severely limited his activities, and in 1930 he decided to specialize in radiology.

Proceeding M.D. in 1930, Calthrop threw himself with zest into the study of radiology, and in 1932 he took the D.M.R.E. After a period in Germany under Albrecht and Berg, he started a private practice which increased at a remarkable rate on account of his superb technical skill and his high diagnostic ability. He rapidly gained hospital appointments, becoming radiologist to the Radium Institute, the Princess Beatrice Hospital, the Charterhouse Clinic for Rheumatism, and the Royal Free Hospital. Between his hospital work and his large private practice he undoubtedly overtaxed his limited physical capacity, and early in 1940 he was compelled to retire. To a person of Calthrop's temperament it was not easy to bow to the inevitable, and after a year's rest he came back to private and hospital practice against medical advice. To his friends, how he contrived to carry on until finally compelled to retire suddenly in 1946 will ever be a matter for amazement and admiration. Calthrop did not write much, but it was mainly due to his efforts that the Berg technique for the examination of the gastro-intestinal tract was introduced and popularized in this country. He is survived by a widow and a young son.

DE GUSTIBUS NON DISPUTANDUM EST (Pr.)

Taste cannot be disputed

The need for iron in cases of pregnancy and post-partum anaemia is generally recognised, yet the form in which it is given must depend on the individual needs of the patient.

Taste cannot be disputed—but a prescription for only three 'Plastules' daily will be found readily acceptable to the patient. They are easy to take and contain ferrous iron in semi-fluid form, sealed fresh in a gelatin capsule. Thus a rapid response without causing digestive upset is achieved.

PLASTULES

Each Plastule is an iron tablet with 1 c.c. of P.P. Semi-fluid form. The tablets are sealed individually in a gelatin capsule with a fresh dose of iron.

'CARBRITAL' CAPSULES

A new Sedative and Hypnotic Combination

In 'Carbital' Capsules the rapid, but relatively brief, hypnotic action of soluble pentobarbitone is combined with the prolonged sedative effect of carbromal, and in insomnia 'Carbital' produces slumber simulating natural undisturbed sleep of adequate depth and duration, and patients awoken refreshed and alert.

'Carbital' is also indicated as a general sedative in neurasthenia, etc.; for pre-operative sedation; in obstetrical practice; and routinely in minor operations.

Each 'Carbital' Capsule contains 1½ grains of soluble pentobarbitone and 4 grains of carbromal.

Issued in bottles of 10, 25 and 250 capsules.

Further particulars on request.

Of Good Repute

ON the considered word of the family Physician many homes benefit by the gentle efficacy of Dinneford's Pure Fluid Magnesia.

This mild laxative and antacid, consisting of Liquor Magnesii Bicarbonatis 2.9% w/v, has long been of good repute in the regulation of acidity in the infant stomach and in that of the delicate adult.

Dinneford's
PURE FLUID **MAGNESIA**

Dr. ARTHUR THOMAS TODD-WHITE died on March 14 at Woodford at the age of 78. The son of William White, historian, he was born at Sheffield in 1869. A student at Guy's Hospital, he qualified M.R.C.S., L.R.C.P. in 1893. He was clinical assistant at Guy's and later house-surgeon at the Lancaster Infirmary before taking up general practice in Lewisham and then in Leytonstone in 1898. While in practice he undertook the duties of clinical assistant at the Golden Square Hospital. He retired in 1946. The last of the old school in the area, he never really adjusted himself to this mechanical age, and he would dwell with obvious pleasure on the more leisurely and spacious days when, as a medical student, he voyaged to Australia in a sailing ship. He will be remembered for his many local activities. He was medical officer to the Post Office, divisional surgeon of the St. John Ambulance Brigade, and medical officer to the Clarnico Fire Brigade. In 1909 he established a scientific and military club for boys, and during the 1914-18 war he was one of the founders of the National Volunteer Reserve and later commanded the 3rd Essex Volunteer Battalion. For many years an active member of the British Medical Association, he was at one time honorary secretary and later chairman of the South-west Essex Division. In 1909 he published a paper in the *Guy's Hospital Gazette* advocating the appointment of a Minister of Public Health, and a later paper published in 1913 under the title "A National Medical Service" anticipated the National Health Service Act of 1946. Beloved by his patients, his wide interests in such varied subjects as geology, archaeology, ornithology, and philately assured him a wide circle of friends. He had outlived many who held him in high esteem, but to those that are left his death will be a sad loss. He leaves a widow, a daughter, and two sons. The daughter and the eldest son are members of the medical profession. The youngest son, Squadron-Leader R. N. Todd-White, was killed in 1943.

Dr. AILEEN MARION SETON POLLOCK, who died suddenly on March 29, had been a student at the London School of Medicine for Women and at St. Mary's Hospital. She qualified in 1927, and joined the staff of the Ludhiana Women's Christian Medical College in the Punjab two years later. On her first furlough in 1935 she took the F.R.C.S. Ed. By 1940 she had been appointed medical superintendent of the Ludhiana Hospital, and two years later she succeeded Dame Edith Brown as principal of the College. Dr. Pollock was well known in Scotland and in India for her work in connexion with medical education in the missionary field.

Dr. ARCHIBALD PATERSON ROBB died on April 3 after a short illness at the early age of 54. Born and educated in Glasgow, he qualified in 1918 in time to take a wartime commission in the Royal Navy. His bent was always towards psychiatry, and before entering general practice he was deputy superintendent at Gartloch Mental Hospital. In 1921 he settled in Edinburgh and carried on an ever increasing practice in the Merchiston district. For him, as for many others, the war years meant extra heavy burdens which he cheerfully undertook, adding to his other duties that of medical officer of a Home Guard battalion. There is little doubt that these hard years took their toll of his health, and some three years ago he had a warning that his strength was being unduly taxed. Some fifteen months ago he retired from practice, but still had sufficient vigour to continue his work on pension boards as consultant psychiatrist and on National Service boards. Dr. Robb had been a member of the B.M.A. since 1923, and was a representative at the Annual Representative Meeting in Dublin in 1933 and in London in 1935. He was chairman of the Edinburgh Division in 1945-6, and served on the I.A.S.C. (Scotland) 1933-4 and 1936-8, and also on the Public Medical Services Subcommittee 1936-7. He was medical secretary of the Edinburgh Panel Committee for ten years. He allowed himself little time for recreation, but the social side of life appealed to him, and whether as host or guest he was happy and anxious to share his happiness. He was able to enjoy only for a brief period his semi-retirement to the village of Duddington. He is survived by a widow and one son.—A. F. W. M.

Mr. HAROLD ROUND died on April 10 at his home in Edgbaston after a long illness. He was born in February, 1878, at Handsworth, and was educated at Aston Grammar School and Birmingham University, after being apprenticed to the late Mr. John Turner. He obtained the L.D.S. in 1900, the B.D.S. of Birmingham in 1901, and in 1902 was one of the first to be awarded the M.D.S. degree for his thesis on fractures of the jaw. He practised in Birmingham, and during the first world war, in collaboration with the late Prof. Billington and the late Mr. Arthur Parrott, was in charge of the jaw centre at the 1st Southern General Hospital. He held a similar post at

Barnsley Hall, Bromsgrove, during the second world war. In 1919 he was appointed honorary dental surgeon to the Queen's Hospital, and when this amalgamated with the General Hospital to form the Birmingham United Hospital he transferred to the Queen Elizabeth Hospital. He was a past president of the Central Counties Branch of the British Dental Association and of the Odontological Section of the Royal Society of Medicine. He was the founder, and twice president, of the Odontological Section of the Birmingham Medical Institute. As recently as last year he became one of the foundation fellows in dental surgery of the Royal College of Surgeons. "H.R." as he was known by his colleagues, was a man of strong principles and firm convictions. He was held in the greatest affection by his friends. He was conscientious to a fault, sparing neither his time nor his skill in the service of his many patients. The writer was closely associated with him for over forty years, and in common with all his colleagues held him in the highest esteem both as a man and an outstanding member of his profession. He was always unhurried, and nothing counted except the work in hand. Nothing would suffice but the very best. He has been known to give up a well-earned holiday because a dental colleague fractured his jaw and sought his aid—a kindness that was only to be expected from him. Harold Round married Miss F. C. Tate, who died last year. Their only son, Dr. J. H. B. Round, died on active service in Palestine. He is survived by two daughters, to whom the greatest sympathy will be extended by his colleagues, patients, and many friends.—R. A. B.

Dr. Catherine Harrower writes. Through the death of Dr. Alison Mary Hunter a great and irreplaceable loss has been sustained, not only by the medical profession, but also by wide sections of the community which she served. Outside her professional duties she did much public work directed towards the welfare of women and children. As chairman of the National Vigilance Society she continued work in which her mother had already established a tradition. Throughout the months of her final illness Dr. Hunter never ceased to take a lively interest in the world outside her sick-room, and many were the personal and professional problems brought by her friends and colleagues for the sure illumination of her keen intellect. Alison Hunter will long be remembered by her many patients and friends for her loyalty, her compassion, and her unflinching readiness to put self aside in rendering help when called upon at any hour of day or night. She loved children and animals and all weak or suffering creatures, and her gallantry during a life of almost incessant hard work, followed by a long and trying illness, will remain an inspiration to all who knew her.

Medico-Legal

"ALKALOSIS" AND THE EFFECTS OF ALCOHOL

At Cambridge recently a defendant who was charged with driving a motor-car while under the influence of drink unsuccessfully pleaded illness as a defence in a case which occupied the court of Cambridgeshire Quarter Sessions, under the chairmanship of Mr. Gerald Howard, for two days—Jan. 30 and 31. The defendant admitted that he had taken some alcoholic drink on the evening in question, but he contended that it was quite insufficient, in a man of his constitution and habits, to affect his driving, and that his condition when arrested was due not to alcohol but to an excess of alkali which he had been taking for digestive trouble.

Dr. Alexander Brown, of Linton, who had been called in by the police to examine the defendant shortly after he was brought to the station, said that he came to the conclusion that the defendant was under the influence of drink. His speech was slurred, his gait unsteady, his pulse rate was 120, and his breath smelt strongly of alcohol. The Romberg test was positive. He was by turns truculent and jocose, and walked about the police station singing snatches of song. In cross-examination Dr. Brown said that he did not test his pupillary reaction, or his knee-jerks, or look at his tongue, or take a specimen of his urine. He was unaware that the defendant had had a duodenal ulcer or that some years ago he had undergone a short-circuiting operation. He had not complained of feeling unwell. The defending counsel asked whether Dr. Brown had considered that the defendant might be suffering not from alcoholism but from alkalosis.

Dr. Brown said that he had not had that condition specifically in mind, but he thought that for alkalosis to simulate alcoholism in its symptoms so large a quantity of alkali would have to be taken that almost no person could take it. He had never seen a case of alkalosis in general practice.

Dr. James Dundas Simpson, of Cambridge, who was called by the defence, said that his attendance had been requested by the defendant at the police station, where he arrived two hours after Dr. Brown had completed his examination. By then the defendant did not appear to be particularly the worse for drink, and the Romberg test was negative. Dr. Simpson's first impression was that drink was the only explanation of the defendant's conduct, and had he not subsequently obtained further information his conclusion would have been the same as Dr. Brown's. He learned later that this man, who had been a patient of his eighteen months previously for duodenal trouble, had been taking, not by his advice, large quantities of a proprietary alkali preparation. On the day of his arrest, according to his story, feeling unwell, he had consumed almost an entire bottle of this substance. His symptoms were consistent with alkalosis. Dr. Simpson had had one other case of alkalosis. This was a man on whom a gastro-enterostomy had been performed, and whose habit it had been for years to take large quantities of bicarbonate of soda. On one occasion he was picked up in a state of collapse, and proved to be quite uncoordinated; he staggered in his gait, was irrational in his speech, was incontinent, and showed such changes in his mentality that anyone observing him, and unaware of the facts, would have judged him to be a drunken man. Dr. Simpson did not suppose that any doctor in this country had any large experience of alkalosis, but it was a possible diagnosis which was tucked away in the mind. The cumulative effect of large quantities of soluble alkali absorbed into the blood stream might lead to a breakdown, either slow or sudden, liable to be precipitated by a chill or other factor. Chemical tests for alkalosis required very sensitive apparatus and were impracticable in an examination such as this at a police station. Many chronic dyspeptics, against their doctor's advice and without his knowledge, consumed much-advertised preparations in order to obtain relief from intestinal pain and discomfort, and the danger of poisoning by alkalis was not to be disregarded.

After a long hearing the jury returned a verdict of guilty on the main charge, and the accused was fined £50. On a second charge, that of driving a motor-car in a manner dangerous to the public, he was also found guilty and fined £1. He was disqualified from holding a driving licence for one year.

Appeal Dismissed

The defendant's appeal against his conviction was heard on April 19. The substantial ground of the appeal was that the evidence given by Dr. Alexander Brown, who was called in by the police, was inadmissible. Mr. Justice Humphreys, giving the judgment of the Court, said that the appellant had been seen driving on the wrong side of the road and without lights, and that on examination by the police he appeared to be drunk. They took him to a police station, and there the ordinary procedure was carried out. Following an order circulated to police stations years ago a police doctor was sent for. This doctor told the appellant that he could have his own doctor. The appellant said that he had never had a doctor in his life. The police doctor then examined the appellant and certified him to be in an alcoholic state and unfit to drive. This evidence was said to be inadmissible. The appellant had not wished to be examined, but kept singing and was awkward. The doctor had eventually persuaded him, saying that an examination might be to his advantage. The doctor had behaved perfectly reasonably. The law which excluded evidence of a confession extracted by means of a promise or threat had nothing to do with this case and the appeal would be dismissed.

Counsel for the appellant had referred to the recent Scottish case of *Perd v. Nixon* (1948) in which the conviction in a similar case had been quashed. The Lord Advocate had then suggested that in all such cases the police doctor was acting on the word of the police. Mr. Justice Humphreys mentioned that fact. Their Lordships did not agree that that was

The Times, April 20.

true in England. The evidence of a police doctor should be accepted in the same way as the evidence of any other professional man. It must be presumed that he came before the Court with the desire to assist it and with no other desire.

Universities and Colleges

UNIVERSITY OF LONDON

The Academic Postgraduate Certificate in Public Health has been awarded to D. Coueslant, T. H. Elias, W. K. Laing, and D. N. Phukan, all of the London School of Hygiene and Tropical Medicine.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

The otolaryngology lecture course which was to have been held at the College from April 26 to May 12, has been cancelled.

SOCIETY OF APOTHECARIES OF LONDON

Prof. E. C. Dodds, F.R.S., Master, presided at a recent meeting of the Court of Assistants, when the resignation of Dr. Cyril H. T. Hott was received with great regret.

The Court considered the present position with regard to the National Health Service and it was resolved to forward a resolution to the British Medical Association expressing the hope that further negotiation between the Minister of Health and the profession would be made possible.

The following were appointed as representatives of the Society: Dr. J. Prescott Hedley, on the Central Midwives Board, and Dr. Frank Howitt at the International Congress on Physical Education, Recreation, and Rehabilitation.

The Gilson Scholarship in Pathology was awarded to Alan C. Thackray, M.D.

It was announced that on July 7 the Society's gold medal in therapeutics will be presented to Sir Lionel Whitby, M.D., F.R.C.P., Regius Professor of Physic in the University of Cambridge.

Authority was given for the Society's Coat of Arms to be incorporated in a memorial window at Westminster Hospital to the late Sir Stanley Woodwork.

Sir Frederick Michael Wells, Lord Mayor of London, was admitted to the Freedom of the Society, the first occasion, it is believed, on which the Lord Mayor of London has been admitted to the Freedom of a City Company during his year of office.

It was resolved that a course of ten lectures on modern therapeutics be delivered in the Great Hall in the autumn.

The Diploma in Industrial Health was granted to A. M. Critchley, D. Fowler, V. O. B. Gartside, A. French, R. Swinburn, and S. A. Underwood.

The Diploma of L.M.S.S.A. was granted to E. F. Jofes, L. T. Al-Badri, M. K. A. El Banhawy, C. F. M. Fisher, W. L. M. Garsia, D. J. Sheerboom, I. F. Dajani, S. K. A. D. J. Bernhardt, E. L. Gilbert, C. K. Cumming, P. C. J. Nicholl, C. H. J. Van Aswegen, M. P. Coplans, and M. J. Bhavnani.

Medical Notes in Parliament

Manor House Hospital

On April 22 Mr. GAMMANS inquired for what reason the Manor House Hospital and the Manor House Clinic, Hampstead, were to be exempted from the National Health Service.

Mr. BEVAN replied that it appeared to him that their transfer was not required for the purpose of providing hospital and specialist services under the Act.

Imported Books

Mr. SWINGLER on April 22 invited the President of the Board of Trade to make a further statement about imports of learned, scientific, and technical books.

Mr. HAROLD WILSON replied that he had been going into this question. He had always been aware of the strength of the case for increasing imports of the classes of books mentioned, although he had to balance this against the exchange position. He was now able to tell the House that learned, scientific, and technical books could, as from April 1, be imported at twice the present rate, thus raising the annual import quota to 200% by value of the pre-war level.

(The need for this increase in the quota allowed to importers was discussed in a leading article in our last issue—p. 793.)

No 15

Last Panel Cheques -- Mr. BESAN, in reply on April 22 to Sir ERNEST GRAHAM-LITTLE said that the payments an insurance doctor would receive for the period Jan 1 to July 4, 1948, would be based on the average of the number of persons on his list on Jan 1 and April 1.

Discussion of Table

In Northern Ireland increases were reported in the notifications of diphtheria 9 and whooping-cough 11, while a decrease of 9 was recorded for scarlet fever and for measles. Measles and whooping-cough reflect the trends of these diseases in Belfast C.B., while the changes in the incidence of diphtheria and scarlet fever were due to the experience of the country areas.

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,290, whooping-cough 3,888, diphtheria 136, measles 9,681, acute pneumonia 639, cerebrospinal fever 47, acute poliomyelitis 19, dysentery 110, paratyphoid 7, and typhoid 9.

are for: (a) The 126 great towns in *England and Wales* (excluding London) (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in *Ire*. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

- * Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.
- † Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.
- ‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.
- § The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.
- || Includes mumps fever for England and Wales and Eire.

Medical News

Papers for the Cambridge Meeting

The reading Opening Papers in the Scientific Sections of the B.M.A. Annual Meeting at Cambridge in June are reminded that their papers, with full summaries, should have been in the hands of the Editor of the *British Medical Journal* on May 1, so that arrangements can be made for the printing of the summaries. Will those who have not yet sent in their papers kindly do so at the earliest opportunity.

Government Reception

The Government held a reception on April 21 at the General Register Office, Somerset House, in honour of the members of the Canadian and United States Delegations concerned with Medical Nomenclature and Statistics. Mr. Aneurin Bevan, the Minister of Health, and Mrs. Bevan received the guests.

Society of Chiropodists

The Society of Chiropodists held a successful Annual Convention in London on April 22, 23, and 24. At a dinner at the Savoy Hotel on Friday, April 23, the many guests were received by the President, Mr. John H. Hanby, who is instructor in chiropody at Guy's Hospital. Sir Heneage Ogilvie proposed the toast of the Society and described the cordial relations between the Society and the Royal College of Surgeons. In his reply Mr. Hanby referred to the importance of chiropody in connexion with the care of school children and in industry. Mr. Charles Challen, M.P., proposed the toast of the medical profession and Sir Alfred Webb-Johnson, P.R.C.S., replied.

Hogarth Centre

The radiotherapeutic centre at the Nottingham General Hospital has been renamed the Hogarth Centre in recognition of the outstanding services of Mr. R. G. Hogarth, who has attained his 80th birthday, in treating cancer. The announcement was made by the Duke of Portland at the annual meeting of the Notts Council of the British Empire Cancer Campaign recently.

Gift to Royal College of Physicians

The British Red Cross and St. John War Organization has given £20,000 to the Royal College of Physicians in recognition of the services rendered to it by the medical profession during the war. It will be used to develop the library, particularly to help students of the history of medicine.

New Journal of Plastic Surgery

The first number of the *British Journal of Plastic Surgery* has been published by the British Association of Plastic Surgeons under the editorship of Mr. A. B. Wallace, of Edinburgh University. It is particularly well produced, the illustrations being remarkably clear. This number contains articles on "Plastic Surgery in the Training of Surgeons," by Mr. Paterson Ross, "Congenital Absence of the Penis," by Sir Harold Gillies, "Deformities of the Male Urethra," by Sir Archibald McIndoe, and other papers by Mr. Rainsford Mowlem, Mr. James B. Cuthbert, Mr. F. T. Moore, and Mr. M. C. Oldfield.

Dentists Request Interview with Minister

The Dental Consultative Committee has asked the Minister of Health for an interview, and also that he consider incorporating amendments in the N.H.S. Act. It requests an Amending Bill to prevent the formation of a whole-time salaried service by Regulation as well as other possible amendments.

National Insurance

After July 5 those medical practitioners on the lists of Executive Councils under the N.H.S. Acts will be classed as self-employed persons for the purposes of paying insurance contributions under the National Insurance Act, 1946 (Preliminary Draft of the National Insurance (Classification) Regulations, 1948).

History of Medicine

At the inaugural meeting of the Scottish Society of the History of Medicine, held on April 23 in the hall of the Royal College of Surgeons of Edinburgh, Dr. H. J. C. Gibson read a paper on "The Early Days of the Dundee Royal Infirmary," of which institution he is now the superintendent. He said that the Infirmary originated as a dispensary which was founded in 1735 and reorganized in 1782 as the hospital of the parish. He was assisted in his philanthropic work by Mr. Stewart, surgeon, and by Sir Alexander Douglas, Bt., president of the Infirmary in 1782. The cost of the original building was £10,000, and for the purchase of surgical instruments, "the most complete and the best of the kind" came from the Government. The building was in poor condition when they travelled from a distance

or had met with dangerous accidents, when they were admitted at any time. The decision on eligibility for admission rested with the Weekly Board. A maintenance charge of 3s. 6d. per week was payable by the Governor who had recommended the patient. Dr. Gibson traced the history of the hospital from those early days to the building of the new Infirmary in 1855, by which time it had become, as it still remains, one of the chief voluntary hospitals of Scotland, serving the needs of patients from Angus, East Fife, and Perthshire.

At the close of his address the speaker was thanked by Dr. W. D. D. Small, President of the Royal College of Physicians of Edinburgh.

Dr. Douglas Guthrie, who has been elected President of the Society, explained that it was founded to create and extend interest in the history of medicine throughout Scotland. The Hon. Secretary, Dr. H. P. Tait, 137, Colinton Road, Edinburgh, will be glad to hear from any who are interested. At the second meeting, to be held in June, Dr. John Ritchie will address the Society on "Quarantine for Plague in the Sixteenth and Seventeenth Centuries."

COMING EVENTS

"Darkness into Daylight"

An exhibition to mark 100 years of research and achievement in electric lighting, entitled "Darkness into Daylight," opens to-day (Friday, April 30), at 10 a.m., at the Science Museum, South Kensington, London, S.W., and will remain open until the end of September. The hours of admission are 10 a.m. to 6 p.m. on week days and 2.30 p.m. to 6 p.m. on Sundays.

Westminster Hospital Ladies' Association

The annual meeting of the Westminster Hospital Ladies' Association will be held in the Queen Mary Nurses' Home of the hospital (entrance in Page Street), on Wednesday, May 5, at 3 p.m., when Emeritus Prof. Winifred Cullis will give an address and the house governor will speak on "The Future Outlook."

Centenary of First Public Health Act

The Corporation of London has arranged a dinner to be held in the Guildhall Library on Friday, May 7, at 6.45 p.m. for 7.15 p.m. to commemorate the centenary of the first Public Health Act.

French Refresher Course

A course devoted to recent advances in medicine will be held on May 21 to 23 at the Clinique Propédeutique of the Broussais Hospital, 96, Rue Didot, Paris. Further information may be obtained from Prof. Jean Hamburger, 29, Boulevard de Courcelles, Paris VIIIe.

Physical Medicine

The British Association of Physical Medicine announces that its Belgian counterpart, La Société Belge de Physiothérapie, has arranged for an International Meeting of Medical Electronics to be held in conjunction with the Journées Médicales in Brussels from June 13 to 16. The object of the meeting is to bring together medical men and physicists and enable them to exchange views on subjects within the following fields: (1) General physics in relation to its application to medicine; (2) photo-biological and electro-biological principles of direct importance to medicine; (3) medical electrology with special reference to diagnosis and treatment; (4) equipment and dosimetry. Those wishing to attend or to make scientific contributions are asked to communicate with Dr. L. Konings, Rue Vilain XIV, 43, Bruxelles, Belgium.

SOCIETIES AND LECTURES

Monday

EDINBURGH UNIVERSITY: PHYSIOLOGY CLASSROOM.—May 3, 5 p.m. "Medicine and Philosophy," by Dr. Douglas Guthrie.

INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY, 330, Gray's Inn Road, London, W.C.—May 3, 2.30 p.m. "Facial Paralysis. Bell's and other Palsies. Nerve Grafts. Nerve Anastomosis," by Miss D. J. Collier.

LIVERPOOL PSYCHIATRIC CLINIC.—At Town Hall, Liverpool, May 3, 3 p.m. Annual meeting. "New Pathways in Psychiatry," by Prof. H. V. Dicks, M.D., M.R.C.P.

WESTMINSTER HOSPITAL SCHOOL OF MEDICINE: MEYERSTEIN LECTURE THEATRE, Horseferry Road, S.W.—May 3, 5.30 p.m. Clinicopathological demonstration. Discussion: "Emphysema."

Tuesday

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE.—At Edinburgh Royal Infirmary, May 4, 5 p.m. "Salt and Water Parallelism," by Prof. Kerpel-Fronius.

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—May 4, 5 p.m. "Dermatophytes," by Dr. I. Muende.

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION.—At B.M.A. House, Tavistock Square, London, W.C., May 4, 8.30 p.m. Social meeting.

UNIVERSITY COLLEGE LONDON: DEPARTMENT OF PHYSIOLOGY.—At Physiology Theatre, Gower Street, London, W.C., May 4, 5 p.m. "The Physiological Aspect of Speech," by Mr. D. B. Fry, Ph.D.

Wednesday

GLASGOW UNIVERSITY: DEPARTMENT OF OPHTHALMOLOGY.—May 5, 8 p.m. "The Growth of Ocular Vessels," by Dr. J. C. Michaelson.
ROYAL SOCIETY OF ARTS, John Adam Street, Adelphi, London, W.C.—May 5, 2.30 p.m. Pope Memorial Lecture: "Recent Advances in Stereochemistry," by Mr. F. G. Mann, D.Sc., F.R.S.

Thursday

EDINBURGH ROYAL INFIRMARY.—May 6, 4.30 p.m. Honyman Gillespie Lecture: "The Experimental and Clinical Use of Anti-Histamine Drugs," by Dr. R. B. Hunter.

FACULTY OF HOMOEOPATHY.—At London Homoeopathic Hospital, Great Ormond Street, London, W.C., May 6, 5 p.m. "The Evolution of Clinical Pathology," by Dr. William Briggs.

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—May 6, 5 p.m. "The Seborrhoeic Eruptions," by Dr. B. Russell.

INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY, 330, Gray's Inn Road, London, W.C.—May 6, 3 p.m. "A Modification of Laryngectomy," by Dr. Jean Leroux-Robert (Paris). Illustrated by a cinematograph film. 5.30 p.m. "Diseases of the Antrum of Dental Origin," by Mr. J. Angell James.

LONDON JEWISH HOSPITAL MEDICAL SOCIETY.—At London Jewish Hospital, Stepney Green, E., May 6, 3 p.m. "Medical Statistics," by Dr. J. Bronowski.

ROYAL PHOTOGRAPHIC SOCIETY.—At 16, Prince's Gate, London, S.W. May 6, 7 p.m. "Photomicrography" Lecture by Mr. F. J. Pitcock, F.R.P.S.

Saturday

INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY, 330, Gray's Inn Road, London, W.C.—May 8, 11 a.m. "Modern Temporal Bone Surgery. The Philosophy of Its Evolution," by Dr. Julius Lempert (New York).

APPOINTMENTS

Percival V. Pritchard, M.D., F.R.C.P.Ed., F.R.F.P.S., has been appointed to the Northern Ireland General Health Services Board.

CHRISTIE, THOMAS, M.D., Medical Officer, H.M. Prison, Holloway.

MARTIN, K. W., M.D., B.S., F.R.C.S., Resident Surgical Officer and Surgical Registrar, Werthing Hospital.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Bard.—On April 14, 1948, at Queen Mary Hospital, Hong Kong, to Sophie Bard, M.R.C.S., L.R.C.P., wife of Dr. S. M. Bard, a daughter.

Brewerton.—On April 5, 1948, at 9, Lancaster Grove, London, N.W., to Sylvia, wife of Dr. R. Brewerton, a daughter—Jane Elizabeth.

Nelson.—On April 15, 1948, at Salisbury General Infirmary, to Albertine (née Van Calk), wife of Maurice P. Nelson, M.R.C.S., L.R.C.P., a son—Robert Francis.

Williams.—On April 20, 1948, at Queen's Clinic, London, S.W., to Lois Carol (née Schaefer), formerly of Evansville, Indiana, wife of Dr. A. H. Williams, a son—Stephen Joseph.

DEATHS

Bruntles.—On April 18, 1948, Oswald Bruntles, L.R.C.P.S. Ed., L.R.F.P.S. Glas., of 75, Denmark Villas, Hove, Sussex, aged 68.

Clarke.—On April 18, 1948, at 2, Wood Villas, Clifton Road, Preswiche, Lancs, Maude Patricia Smart Clarke, M.B., B.Cn.

Cuthbert.—On April 24, 1948, at Hindhead, Surrey, Margaret Jane Modie Cuthbert, M.B., Ch.B.

Fleming.—On April 10, 1948, Thomas Loudon Fleming, M.B., Ch.B., aged 60.

Forre.—On April 19, 1948, at Boscombe Hospital, George Raynton Forre, M.R.C.S., L.R.C.P., of Handley, Dorset, aged 76.

Gardiner.—Recently, John Percival Gardiner, M.B., Ch.B. Ed., of Pendine, near Penzance, Cornwall.

Gleghrie.—On April 15, 1948, Norman William Gleghrie, M.B., Ch.B. of The Hall, Blorwich, Staffs.

Glass.—On April 21, 1948, at The Shering, Grantown-on-Spey, Alexander Gibb Glass, M.D. Ed., formerly M.O.H., Farnworth, and late of Bolton, Lancs.

Goddard.—On April 20, 1948, Gerald Hamilton Goddard, D.S.O., M.R.C.S., L.R.C.P., Lieutenant-Colonel, R.A.M.C.

Grapel.—On April 20, 1948, Francis Gaspar Grapel, M.R.C.S., L.R.C.P.

Guttmann.—On April 25, 1948, Eric Guttmann, L.R.C.P.S. Ed., L.R.F.P.S. Glas., of Maudsley Hospital, London, S.E., aged 52.

Hill.—On April 14, 1948, at 21, Mapdala Road, Nottingham, Philip Keith Hill, M.R.C.S., L.R.C.P., aged 65.

Lidderdale.—On April 20, 1948, at Cheltenham General Hospital, William Guy Lidderdale, M.B., B.S., of Shillington, Hitchin, Herts.

Marlin.—On April 19, 1948, at Hove, Mary Edith Marlin, L.R.C.P.S. Ed., L.R.F.P.S. Glas., aged 72.

Newport.—On April 19, 1948, Alexander Charles William Newport, C.V.O., M.R.C.S., L.R.C.P., Surgeon Captain, R.N., retired, of 17, Cousins Grove, Southsea.

Temple.—On April 19, 1948, at Knockdolian, Comrie, Perthshire, Charles Dunbar Temple, M.B., C.M. Glas., aged 85.

Thomson.—On April 16, 1948, at Derbyshire Royal Infirmary, George Thomson, M.B., C.M.

Williams-Walker.—On April 22, 1948, at 56, Anderton Park Road, Moseley, Alfred Williams-Walker, M.D., M.R.C.P.

Wrigley.—On April 26, 1948, at a Huddersfield Hospital, Kenneth Graham Wrigley, L.M.S.S.A., aged 53.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Normal Blood-pressure Readings

Q.—What do you consider to be the normal systolic, diastolic readings for adults under 50, aged 50 to 65, and over 65 years of age? It appears to me that, according to the tables of insurance companies, the majority of patients over 50 have hypertension. Textbooks advise prohibition of alcohol and drastic reduction in salt for patients suffering from arteriosclerosis or hypertension. Is there anything to be gained by compelling patients over 65, with hardening of arteries and/or some rise in blood pressure, to forgo the pleasure of using salt and alcohol as their inclination suggests? Is there not some risk in depriving patients of salt over a long period?

A.—This reply deals not with casual but with basal readings—i.e., those found at repeated examinations under resting conditions. The upper limits of normal pressure for adults at various ages are: below 50, 150/90 mm. Hg; between 50 and 65, 155/95 mm. Hg; and over 65, 160/95 mm. Hg. Pressures above the last figure represent hypertension at any age, although slight excesses are of less and less significance in later ages. For life assurance examinations the blood pressure is best registered after a few minutes' recumbency, the lowest of two or three recordings being taken. The type of case described in the last half of the question does not require prohibition of alcohol or drastic salt restriction, although both articles should be kept well within moderate limits. The degree of salt restriction obtainable by avoidance of salt in cooking and at table is without risk even over a long period.

Animal Ringworm in Farm Workers

Q.—Recently I have had several cases of animal ringworm in farm workers. Is there more than one kind of animal ringworm, and does it affect all persons in the same way, as the lesions appear to differ? Liquor iodi fortis, ung. hydrarg ammon. co., and ung. iodi B.P. have all been tried without much success. Is treatment by x rays of any value?

A.—Animal ringworm may be of many types, both small-spore and large-spore, but most of the cattle ringworm infections are of the large-spore ectothrix variety. The small-spore varieties produce very little more inflammation on the skin than does the ordinary human small-spore infection, but large-spore infections produce varying degrees of inflammatory reaction, with redness, vesication, and pustulation right up to the type of lesion described as kerion, with great swelling, oedema, and congestion, and a follicular pustular reaction over the area involved. The fierce reaction is a natural response to the foreign invasion, and is part of the mechanism of cure. The introduction of local treatment will sometimes precipitate such a pustular reaction. The most effective local applications are ung. dihydran B.P. and the following paint, fomentations often being necessary:

B	Hyd. perchlor.	40
	Brilliant Green	10
	Spirit	ad 100%
	Make a paint.					

X rays are of no value in the treatment of ringworm infections in these cases.

Discoloration of Adrenaline Solutions

Q.—What changes cause the discoloration of solutions containing adrenaline? How do these changes affect the physiological action of the drug? Should the solution be acid to prevent discoloration? What substances are used to prevent deterioration?

A.—The darkening in colour of a solution of adrenaline is caused by the gradual decomposition of the adrenaline hydro-

chloride in it; this naturally reduces the activity of the solution, and it eventually becomes inert. It is necessary to have the solution slightly acid, in the first place because adrenaline itself is only very sparingly soluble in water and must be converted to the hydrochloride or another salt, and secondly because it is more stable in somewhat acid solution. Various substances may be used to prevent or retard the decomposition of adrenaline. Sodium metabisulphite in a concentration of 1 in 1,000 is the chemical favoured at present, but other antioxidants are useful, and glycine in a concentration of 1 in 500 is also effective.

Thorotrast and Sarcoma Formation

Q.—Is there any evidence that the intravenous injection of "thorotrast" may lead to sarcoma formation at a later date?

A.—Yes. Several authors, including G. Roussy, C. Oberling, and M. Guérin (*Bull. Acad. Méd., Paris*, 1934, 112, 809), have shown that the injection of thorium dioxide may produce sarcoma in experimental animals, and especially in the rat. More recently H. E. MacMahon, A. S. Murphy, and M. I. Bates (*Amer. J. Path.*, 1947, 23, 585) have provided evidence which, although derived from a single case, nevertheless indicates that thorotrast may also act as a sarcomagenic agent in man. The patient had been given thorotrast intravenously for visualization of the liver, and by this means it was possible to make an accurate diagnosis of hepatic syphilis with gumma. Following specific therapy the patient made a clinical recovery. After sudden death twelve years later, necropsy confirmed the diagnosis of syphilis and in addition revealed fatal haemorrhage from a sarcoma of the liver, with widespread irradiation injury chiefly affecting the liver and the haemopoietic system.

Introduction of Cholera into Egypt

Q. How did cholera get to Egypt last September?

A.—Despite the fullest inquiry and investigation by the Egyptian Government the source and mode of introduction of cholera into Egypt last September were not discovered. It seemed likely that infection had been occurring before the first cases were recognized in an Egyptian village on Sept. 22, 1947. The infection presumably came from one of the endemic regions in India, from which in the past there were three possible routes to Egypt: (1) the long land route through Afghanistan and Iran—nowadays most unlikely; (2) by the Persian Gulf to Irak and on to Syria and the Mediterranean; (3) by the Red Sea direct to Egypt. To these must nowadays be added the air routes from India via Egypt and Arabia. In spite of rumours and allegations there was no evidence to suggest that the Royal Air Force or the British Army was responsible for last year's introduction of cholera into Egypt.

Antrochoanal Polypi

Q. Are antrochoanal polypi usually associated with anosmia? In a case in which the antra have been cleared the anosmia persists. What treatment is advised?

A.—Antrochoanal polypi are not, as a rule, associated with anosmia. They are almost invariably unilateral, and to cause anosmia mechanically must be large enough to block both choanae completely. If the ethmoids are clear probably no further treatment will help.

Renal Rickets

Q. A woman 28 years old suffered from rickets at the age of 14 years, and is now a typical "rickety dwarf." At the age of 28 is there any possible hope of straightening the bones or the feet by operation?

A. If this patient is suffering from ordinary rickets due to lack of vitamin D there is no reason at all why the legs should not be straightened by osteotomies. The age of onset, however, and the fact that she is a dwarf strongly suggest that she may have "renal rickets." In these patients kidney function is impaired, and an anæsthetic or an operation will often precipitate a fatal uræmia. Therefore, before any decision is made to operate, renal function should be thoroughly

Penicillin for Actinomycosis

Q.—What is the recommended dose of penicillin for actinomycosis?

A.—The dose of penicillin should be large and should be continued for a long time: 250,000 units every six hours or 500,000 twice in the 24 hours would be about the dose necessary for a severe infection of thorax or abdomen. Half that dose would probably suffice for a face or neck infection. The drug must be administered for a month or two continuously. When given in concentrated form the injections are not too painful, but procaine hydrochloride should be put in the syringe in order to diminish the discomfort.

NOTES AND COMMENTS

Liquid Paraffin for Cooking.—Mr. P. ROCHE, Editor of *The Retail Chemist*, writes: Although the answer to the inquiry made under this heading (April 17, p. 769) recommends that "its use [liquid paraffin] as a substitute for vegetable oils in salad creams and cooked products generally should be prohibited by law," it does not indicate that there is still in operation a Government Order which deals with this very point. I refer to the Control of Petroleum Order, 1944, S.R. & O. 1944, No. 171, which says in effect that no person shall use any liquid paraffin (B.P.), except for medicinal purposes, except when having a licence to do so. Obviously any general member of the public using this substance for the purposes you mention is breaking the law, and, although one can assume that it has been contravened time and time again, I doubt whether an offender has yet been charged, although the Order has been in force now for over four years. This seems to be another instance where the multiplicity of Orders precludes their being effectively enforced, presumably because of the lack of inspectors. Even if there were sufficient, which heaven forbid, it would not be easy to see that every housewife used liquid paraffin for medicinal purposes only, particularly when she can buy it with no questions asked. The matter takes on another serious aspect when supplies have reached the fixed price stores and yet the dispensing chemist has not been able to obtain sufficient to meet prescription requirements. Would it not be better, therefore, if the channel of distribution is limited to that of the chemist, who can at least obtain a verbal acknowledgment that the liquid paraffin he sells is going to be used for "medicinal purposes" only?

Killing Habits of Leopards.—A correspondent in W. Africa writes: Under "Any Questions?" (March 13, p. 530) you answer a question about leopards. I think I can help in answer to (d). Some years ago a woman was brought into hospital with a cut head. On inquiry I found that a leopard had jumped at her and had given her one blow with its paw—claws extended. She had a small puncture just above the middle of one clavicle, a clean cut through the ear and right across the scalp to the other ear, and two quite clean cuts parallel to this one and about two inches in front and behind it. They were about four or five inches long. As far as I could make out the puncture in the neck was made by the fifth claw, the main cut by the middle claw, and the other two by the index and ring fingers (if leopards have such things). The woman was almost scalped, and was shocked. She had not lost much blood. Cleaning with flavine and suturing were followed by rapid healing. It appeared that the leopard had been disturbed by the woman and had given her a pat in self-defence. There was no suggestion of "leopard men" in that area. The cuts were very clean.

Corrections

The name of the Medical Director of the Empire Medical Advisory Bureau was misspelt in our issue of April 24 (p. 809). It should be Dr. H. A. Sandiford.

In the letter by Dr. I. H. Milner (April 24, p. 807, line 10) the word "complicated" should be "uncomplicated."

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Atiology, Westcent, London*. ORIGINAL ARTICLES AND LETTERS forwarded or publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required, as proofs are not sent abroad. SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY MAY 1 1948

MEDICINE AT CAMBRIDGE

BY

C. H. WHITLE, M.D., F.R.C.P.

We publish below some notes on the University of Cambridge and the Medical School which may be of interest to members of the Association attending the Meeting.

The town of Cambridge probably owes its origin and importance to its strategic position as a fort (Castle Hill) guarding the crossing of the river over or through which lay the main line of communication between the Midlands and the Eastern Counties. To the north below this crossing were the relatively impassable Fens, though the river was navigable and Cambridge, until quite recent times, a port in daily communication with the sea via King's Lynn and the Wash. There is plenty of evidence that even before the twelfth century monasteries existed in or near the present site of the town. St. Rhadegunds was a nunnery standing where Jesus College now stands, and there are still remains of the old buildings. Of Barnwell Priory little is left, but the delightful Lepers' Chapel with some well-preserved Norman work marks the site, close by the bridge where the Newmarket Road crosses the railway a mile out of the town.

It seems more than likely that the monasteries were the centres of study and teaching in the neighbourhood for several centuries, and so it was that the place was gradually sought out as a seat of learning. A "grammar school" may well have preceded the appearance of the colleges, but there is no doubt that the collegiate system proper was started by Hugh de Balsham in 1284 when he founded St. Peter's College, now Peterhouse. There followed Michael House (1324) and King's Hall (1337), both later absorbed into Trinity College, the former to become part of the kitchens. Then came in fairly rapid sequence Clare Hall (1326), Pembroke Hall (1347), Gonville Hall (1348), Trinity Hall (1350), and Corpus Christi College (1352). Nearly a century elapsed before the foundation of King's College (1441), and Queens' College (1448), the latter in the plural because it was founded by two queens—Margaret of Anjou, wife of Henry VI, and Elizabeth Widwife, wife of Edward IV. There followed St. Catharine's (1475), Jesus (1496), St. John's (1511), Magdalene (1542), Trinity College (1546), Emmanuel (1584), and Sidney Sussex (1594). There is another long gap, over two hundred years, before Downing College (1800), and then follow the two women's colleges, Girton (1872) and Newnham (1875), and finally Ridley Hall (1881) and Selwyn (1882).

The older colleges are of great interest by reason of both their history and their buildings. Queens' has its early association with Erasmus (1510), after whom are named the turret and rooms below on the south side of the college; it has also the serene and mellow beauty of the Cloister Court. There is King's Chapel, in which the grandeur of the perpendicular style, especially the windows and fan vaulting, and the glory of the stained glass are unsurpassed anywhere in the world. There is Trinity with its spacious Great Court; and the gentler but no less loveliness of its two smaller neighbours, Trinity Hall and Clare. There is St. John's with its dark Tudor brick, its cobbled courts, and its wide vista over the "Backs"; Magdalene with its smaller courts and more intimate charm, and its Pepysian Library. Other colleges, though they lack the

unique setting which the river with its lawns and trees can give, have other features of equal interest both historical and architectural. Christ's has its delightful courts and its memories of John Milton (1625), whose mulberry tree is still standing—with the help and support fitting to one of ripe years. Emmanuel nourished John Harvard, the founder of the American university. There is a fine new court, by Stokes and Drysdale, and behind the older part of the college lie beautiful gardens with lakes and, in the Fellows' Garden, a swimming-bath, the water being originally brought via Hobson's conduits from the Gogs, the chalk hills near by. These conduits are an unusual and attractive feature of the town, flowing as they do down the main thoroughfares of St. Andrews Street and Trumpington Street. The name derives from Thomas Hobson, one-time Mayor of Cambridge, whose "choice"—of a horse in the first instance—gave rise to the phrase. When horses were the only means of transport he kept a large number for hire, but such was his prosperity he could and did dictate to his customers which mount they should ride: they were never allowed to choose—hence "Hobson's choice". His portrait hangs in the Guildhall. Downing College, with which the Downing Chair of Medicine was founded, is noteworthy for its open spacious grounds and its uniform classical style of building, a feature possibly less pleasing to the modern eye than it was to its designers. There is much of interest to be found in the other colleges, but space does not permit their mention here.

Medical Teaching

The University was recognized in 1318 by a Papal Bull (Pope John XXII), and faculties of divinity, law, and medicine were instituted probably soon after this. In 1421 "Scolles of Fyisk" of some repute were known to exist, because in that year a petition was made to Parliament urging the restriction of practice to those who had graduated in the faculty in their respective universities. It was also then enacted that no woman should be allowed to practise physic—an idea that has been an unconscionable time a-dying, for it was not till over five hundred years later, 1947, that women were admitted to full degrees at Cambridge.

The first M.D. was recorded in 1460; M.B. in 1466. In the sixteenth century there were many M.D.s and M.B.s as well as M.L.s, the latter taken as a qualifying examination. Early in the century Linacre's influence is apparent, for it was at his suggestion that Henry VIII founded the Royal College of Physicians (1518) in London, and in Cambridge the Linacre lectureship at St. John's College. This college was for a long time the chosen training ground for physicians, but towards the middle of the century the fellows were wont to take their duties lightly, and the lectureship came to be regarded as a sinecure. Regius Chairs in Physic, as well as in Divinity, Civil Law, Hebrew, and Greek, were founded in 1540 by Henry VIII, but in spite of this medicine did not prosper for some years. Most of the teaching in physic consisted in expounding the works of Hippocrates, Galen, and Aristaeus. The experimental method was unknown until the eighteenth century, and it was not until much later that our present methods of teaching and examining were begun. From 1570 onwards medical students were no longer required to take Arts before starting their medical course, but even so they usually spent seven years on the M.B. and another five years on the M.D. courses.

The seventeenth century, marked by corruption, sinecures, and poverty of ideas, was followed by some revival of intellectual activity. In 1705 Viganì set up a chemical laboratory

Senate House

[University Cameras

in Trinity College, and Stephen Hales used this laboratory later for experimental physiology—probably the first physiological laboratory. The health and vitality of the medical school from then on seem closely tied to the growth and development of natural science in the University, especially chemistry, physics, and physiology. Chairs were founded in anatomy, botany, and experimental physiology. In 1734 or thereabouts William Heberden the elder was giving the Linacre Lectures in the anatomy school.

In 1819 lectures on special and general pathology and clinical medicine were started, and from then onwards a period of two years' attendance at a hospital away from Cambridge was required before a candidate could sit the final M.B. This was increased in 1841 to three years, which followed three years' study at Cambridge. In 1842 the practical clinical examination was introduced into the final M.B., and towards the end of the century there were many outward signs of the great increase in size and importance of the school. New chairs were created in physiology (Michael Foster), pathology (C. S. Roy), surgery (George Humphry); and lectureships in botany (Francis Darwin), animal morphology (Adam Sedgwick), physiology (W. H. Gaskell, J. N. Langley, and Sheridan Lee), medicine (Donald McAlister), surgery (G. E. Wherry), midwifery (R. N. Ingle), and medical jurisprudence. This wave of new posts in medical sciences was a clear bid for a full clinical teaching school—probably originating in the mind of Humphry—but many of them were suppressed later and the plan was not allowed to mature.

Queens' College

[University Cameras

There were at one time two chairs in medicine, the Regius Professorship and the Downing Professorship. The latter was founded about 1800 with the founding of the college of that name, which was at first intended exclusively for the study of medicine and law. But the chair was suspended on the death of Bradbury in 1930 after his thirty-six years' tenure of the office. The first holder was Busick Harwood, who was a Fellow of the Royal Society and much interested in blood transfusion, which he demonstrated on animals. He was evidently something of a wit and there are several instances recorded. Once on being greeted by Sir Isaac Pennington, the Regius Professor, with, "Good morning,

ing, Sir B-U-sick?" he immediately retaliated with, "Sir I-sic? I never was better in my life!" They were both keen musicians and often played duets together, hence the rhyme:

"Sir Busick, Sir Isaac,
It would make you and I sick,
Sir Isaac, Sir Busick,
To list to your music."

Professors of Medicine

The first of the twenty-two regius professors was John Blyth, appointed in 1540. Of the earlier holders of the Chair* Francis Glisson (1636) was the most distinguished and is the best known to posterity. He was also President of the Royal College of Physicians and a Fellow of the Royal Society. It was about this time that William Harvey, who had studied at Caius College, Cambridge, but had been engaged in experimental research elsewhere, published his revolutionary findings on the circulation of the blood (1628). Glisson was one of the first of Harvey's contemporaries to accept his views, but like many another of his predecessors and successors he spent much of his time out of Cambridge. He studied and wrote a great deal, and it was his *Anatomy of the Liver* that left his name to us in "Glisson's capsule," though his work on muscle irritability marked an even more important advance in the field of physiology. He was a fellow of Caius, a college which superseded St. John's as a centre of medical interests. At least seven other regius professors were either scholars or fellows of Caius.

The next outstanding figure in the Chair of Physic did not appear till much later. George Paget (1839 onwards), whose bust is in the Hospital, together with George Humphry and Michael Foster, was largely responsible for the train of events which raised the medical school to its present prosperity and fame. The tradition was further enhanced by his distinguished successors, Clifford Allbutt, Humphry Rolleston, and Langdon-Brown. Though no longer with us in the flesh, they are much more than names to hundreds still alive who benefited from their example, their teaching, and their personal friendship.

Allbutt was the first physician practising outside Cambridge to be invited to the Chair. He was shortly after elected a Professorial Fellow of Caius College, at which he had previously been a Scholar and from which he had graduated. His work on cardiovascular disease, visceral neuroses, and many other subjects is well known and forms the foundation of our knowledge in these fields. He also invented the present form of clinical thermometer—a great advance on the 10-inch weapon used for the purpose up to that time. There is a portrait of Allbutt by Orpen in the Fitzwilliam Museum, subscribed for by the medical profession and presented at the last annual meeting of the B.M.A. to be held in Cambridge, in 1920. It is an interesting study, but lacks the warmth and kindliness which

*A point of interest, not generally known, is that there is an actual chair handed down to each new occupant of the post. This chair is now in the Master's Lodge, Downing College, for the use of the present Regius Professor, Sir Lionel Whitby.

HEARD AT HEADQUARTERS

"Prescribed Disease"

The Ministry of National Insurance proposes that when a claim for benefit under the National Insurance (Industrial Injuries) Act is made by a workman on the ground that he is suffering from a "prescribed disease" the claim shall be referred to a practitioner for examination and report. The Ministry is drawing up a list of practitioners to be called upon to undertake these examinations, using at the outset the services of examining surgeons appointed under the Factories Acts. In appropriate cases a consultant will be associated. B.M.A. representatives with representatives of the Association of Certifying Factory Surgeons are in conversation with the Ministry on the fees to be paid for such examinations.

The Aged and Infirm

The Association's Report on the Care and Treatment of the Elderly and Infirm has been widely circulated (incidentally to every member of Parliament), and both its formal and its popular editions have been welcomed. The Committee, however, has not ceased its work, and it is reassembling, after almost a year's intermission, to consider how to further its previous recommendations. One of the reports which it has before it is an excellent document prepared by a committee of the Liberal Party, which will come before the party conference at Blackpool this month. One member of the B.M.A. Committee, Lord Amulree, is also a member of the committee which prepared the Liberal Party report. The Committee has also a report by one of its members, Dr. E. B. Brooke, on the place of the out-patient department in caring for old people. Dr. Brooke believes that an important part could be played by the out-patient department in any co-ordinated scheme. With the help of the almoners and the department of physical medicine, and a transport organization, it would not only assist the old people but would lessen the strain on hospital beds.

Income Tax Deductions

Possibly income tax inspectors are not as indulgent on this side of the Atlantic as they are on the other, but here is a list of items which a medical journal in the U.S.A. publishes as the major income tax deductions which the Government allows doctors: amounts paid for preparation of tax returns and estimates and auditing generally; motor-car costs; bad debts; business expenses; club subscriptions if necessary to maintain professional contacts; expenses incurred in collecting professional accounts; contributions (up to 15% of gross income) to charitable, educational, scientific, and other organizations; cost of travel to and from conventions, and subsistence; depreciation on professional property; entertainment costs incurred to benefit practice; equipment, such as books, instruments, etc.; gifts, if made to benefit practice (such as candy, cigars, flowers); interest on loans and mortgages; insurance premiums; journals; litigation expenses in connexion with practice; licence fees, medical or driving; losses not covered by insurance; maintenance cost of surgery; medical society subscriptions; moving expenses; rent for professional quarters; repairs; salaries to secretaries and other employees; dressings, drugs, x-rays, etc.; office supplies; certain taxes (other than income tax itself); and telephone and telegraph costs. It looks as if, instead of any tax being payable when all these deductions have been made, the income tax authorities will have to make a handsome contribution to the doctor.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union.

Municipal Councils.—Fulham, Hackney, Poplar, Tottenham, Tottenham and Waltham. *County Councils.*—Dartford, Radcliffe (limited), Waltham, Waltham. *Other Authorities.*—Denton, Droylsden, Houghton-le-Spring, Huddersfield, Portlough, Redditch (restricted to certain employees), Telford, Walsley, Walsley and Walsley.

Correspondence

Welsh Association of Hospital M.O.s

SIR.—An association of full-time hospital medical officers has been formed within the Welsh Region as the result of the following considerations.

In the past the interests of hospital medical officers have been the concern of the Society of Medical Officers of Health, the Association of Medical Superintendents, and the Association of Municipal Specialists, acting through the British Medical Association. The impending separation of medical officers of health from hospital activities makes opportune the formation of a directly representative association to promote the interests of full-time hospital medical officers and to be available within the region for consultation in all aspects of hospital practice. The Association is called the Association of Hospital Medical Officers (Welsh Region), and membership is open to medical superintendents, consultants and specialists, and medical officers of registrar grade and above. Associate membership is open to junior medical officers of hospitals.

It is hoped that other regions will form similar associations and that these will ultimately amalgamate to form a national body having a recognized status within the British Medical Association. The Secretary will be pleased to hear from regions where similar activities are contemplated or are actually in being.—I am, etc.,

East Glamorgan County Hospital,
Church Village, Pontypridd.

P. T. BRAY.
Secretary

Petrol Ration

SIR.—It is to be hoped that the Association will protest against the proposed cut in the allowance of "essential" petrol to counteract the basic ration. This is the more necessary as our recent applications have been drastically cut, presumably because the superior persons employed by the Ministry of Fuel regard us as rogues and vagabonds and not worth a tinker's cuss.—I am, etc.,

H. E. GIBSON.

H.M. Forces Appointments

ARMY

Major-General N. Cantlie, C.B., M.C., K.H.P., late R.A.M.C., to be Lieutenant-General.

Colonels (Temporary Major-Generals) F. Harris, C.B.E., M.C., K.H.S., and K. A. M. Tomory, O.B.E., and Colonels O. C. Link, A. E. Richmond, C.B.E., K.H.S., T. Young, O.B.E., F. R. H. Mollan, O.B.E., M.C., D. Fettes, O.B.E., K.H.S., T. Menzies, O.B.E., H. T. Findlay, and J. Bennet, K.H.P., late R.A.M.C., to be Brigadiers.

Colonel (Temporary Major-General) J. J. Magner, M.C., late R.A.M.C., to be Major-General.

Colonel S. Smith, late R.A.M.C., has retired on retired pay. Colonel J. T. Simson, retired, re-employed, late R.A.M.C., on ceasing to be employed has reverted to retired pay.

Lieutenant-Colonels E. P. N. Creagh, G. E. MacAlevey, C.B.E., D.S.O., M.C., C. P. Chambers, and V. J. Perez, O.B.E., from R.A.M.C., to be Colonels.

ROYAL ARMY MEDICAL CORPS

Major H. M. Alexander having attained the age limit for retirement is retained on the Active List (Supernumerary).

Captains H. Foster, J. Duguid, and J. N. Threlfall to be Majors. Captain T. C. R. Archer, from Short Service Commission, to be Captain, retaining his present seniority.

Short Service Commission.—Lieutenant A. W. Morrow, from Emergency Commission, to be Lieutenant.

REGULAR ARMY RESERVE OF OFFICERS

ROYAL ARMY MEDICAL CORPS

Major S. H. Smith, M.C., having exceeded the age limit of liability to recall, has ceased to belong to the Reserve of Officers.

Captain (Brevet Major) B. Malaher, having exceeded the age limit of liability to recall, has ceased to belong to the Reserve of Officers on account of disability.

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

Major S. W. Barber has been granted the acting rank of Lieutenant-Colonel.

Captain (War Substantive Lieutenant-Colonel) J. L. Lovibond to be Major.

Captains (War Substantive Majors) F. V. Allen, O.B.E., W. H. Valentine (from R.A.R.O.), S. S. Chessier, and F. J. Fowler to be Majors.

Captains A. Wilcox, A. H. M. Richards, T. MacGregor-Gibson, J. MacM. Macfie, and N. H. H. Longton to be Majors.

Lieutenants (War Substantive Majors) G. Y. Feggetter and H. J. Groot, from Emergency Commissions, to be Captains, and have been granted the acting rank of Lieutenant-Colonel.

Lieutenants (War Substantive Captains) J. R. Macintyre and D. T. Rowlands, from Emergency Commissions, to be Captains, and have been granted the acting rank of Major.

Lieutenants (War Substantive Captains) S. A. Bower, M. A. Watson, G. R. Cubitt, A. H. Bulleid, D. E. Marmion, G. H. Sanderson, W. J. Atkinson, E. J. Williams, G. V. Cole, H. J. Gilbert, A. A. Pow, R. B. Raffle, G. H. A. Robinson, R. McI. Archibald, and J. G. A. Gilruith, from Emergency Commissions, to be Captains.

Lieutenant (War Substantive Captain) C. D. Rigg to be Captain

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

War Substantive Major A. A. G. Lewis has relinquished his commission on account of disability and has been granted the honorary rank of Lieutenant-Colonel.

War Substantive Captain E. C. Fernandes has relinquished his commission and has been granted the honorary rank of Major.

War Substantive Captains M. Singh and G. A. Sharpe have relinquished their commissions and have been granted the honorary rank of Captain.

Lieutenant T. J. Anthony to be Captain

R. A. Roberts to be Lieutenant

WOMEN'S FORCES

EMPLOYED WITH THE R.A.M.C.

Captain M. D. Cameron has relinquished her commission on account of disability and has been granted the honorary rank of Captain.

ROYAL AIR FORCE

Air Commodore P. C. Livingston, C.B., C.B.E., A.F.C., to be Air Vice-Marshal.

Group Captain P. A. Hall has reverted to the retired list retaining the rank of Air Commodore.

Group Captain G. H. H. Maxwell has retired.

Wing Commanders J. Magner, R. G. Freeman, and P. B. L. Potter, O.B.E., to be Group Captains (Substantive).

Squadron-Leaders R. D. Bruce, A. B. Marshall, F. V. MacLaine, R. C. O'Grady, S. Paul, R. L. Scott, and E. B. Harvey to be Wing Commanders (Substantive).

To be Squadron-Leaders: J. W. H. R. Cran, D. Stevenson, M.B.E., J. C. Bowe, and D. W. Boatman.

To be Flight-Lieutenants: M. Alms, G. Ansell, G. R. Carr, K. N. V. Palmer, B. H. Pickard, R. D. Poole, H. Wainslead, J. A. Wheeler-Bennett, J. A. Cooney, C. J. W. Soutar, E. S. Odbert, A. E. Carter, L. Wolman, and P. J. Macnamara.

Flight-Lieutenants (Substantive) R. Mortimer and D. Stevenson, M.B.E., have relinquished the war substantive rank of Squadron-Leader.

Flying Officer P. D. Sutton, M.B.E., to be Flight-Lieutenant

To be Flying Officers: T. C. L. Brown and seconded to the Hospital of St. Cross, Rugby; A. R. P. Calder and seconded to St. Thomas's Hospital.

To be Flying Officers: J. W. Baker, R. E. Blakey, C. I. Cooling, J. G. Hamilton, M. J. Hargrave, T. K. Lamballe, F. I. Locke, R. G. C. MacLaren, R. J. Smith, P. J. Banks, D. O. Davies, I. D. Findlay, J. J. Fingard, G. W. Korn, R. J. Moylan-Jones, T. N. Riley, P. Satlin, and R. J. Whitwell.

ROYAL AUXILIARY AIR FORCE

D. Turner to be Flight-Lieutenant in the reconstituted R.A.A.F.

ROYAL AIR FORCE VOLUNTEER RESERVE

Flight-Lieutenants R. N. Houlton and D. H. Fowler have resigned their commissions retaining the rank of Squadron-Leader.

Flight-Lieutenant W. E. Robinson has relinquished his commission on account of medical unfitness for Air Force service retaining his rank.

D. W. James to be War Substantive Flight-Lieutenant.

Flying Officers H. M. Kent, G. N. Beck, A. W. Halfhide, D. P. Howarth, H. E. M. Kay, D. M. Kerslake, C. Melver, J. K. Oates, A. T. Richardson, G. P. Paddle, F. W. R. Seward, D. W. Stuart, T. F. Waters, R. R. Davis, A. J. Fouracre, N. L. Gilburn, J. Hearty, M. S. Hughes, G. A. S. Lloyd, W. Lyons, P. Mackenzie, R. W. Watson, and D. Watson, to be Flight-Lieutenants (Substantive).

The notification concerning E. S. Odbert in a Supplement to the London Gazette dated Jan. 20, p. 500, col. 2, has been cancelled.

The notification concerning J. McA. Taggart in a Supplement to the London Gazette dated Jan. 27, p. 656, col. 1, should have read J. McA. Taggart.

The notification concerning J. W. Moffitt in a Supplement to the London Gazette dated Feb. 17, p. 1119, col. 1, should have read J. W. R. Moffitt.

The notification concerning G. I. Tewfik in a Supplement to the London Gazette dated Jan. 27, p. 656, col. 1, has been cancelled.

Flying Officers G. I. Tewfik and L. W. Oxenham have relinquished their commissions on account of medical unfitness for Air Force service, retaining their rank.

WOMEN'S FORCES

EMPLOYED WITH THE MEDICAL BRANCH OF THE R.A.F.

Flying Officers J. H. Kelly and M. A. McGrath to be Flight-Lieutenants.

The following have been granted the substantive rank of Flight-Lieutenant: E. C. Baird, B. D. Lee, M. E. McClelland, E. M. McKechnie, E. M. I. Milne, L. G. Moore, M. Robertson, E. M. D. M. Scott, M. E. G. Sherwell, and E. D. L. Simpson.

B.M.A. LIBRARY

The following books have been added to the Library.

Altenburg, E.: Genetics. 1945.

Bach, T. F. (Editor): Arthritis and Related Conditions. 1947.

Bankoff, G.: The Conquest of Brain Mysteries. 1947.

Carr, M. W.: Dentistry, and agency of health service. 1946.

Coope, R.: Diseases of the Chest. Second edition. 1943.

Daley, R., and Miller, H. G. (Editors): Progress in Clinical Medicine. 1943.

Das, K.: Clinical Methods in Surgery. 1947.

Dearden, H.: Creation's Heir. 1947.

Denny-Brown, D.: Handbook of Neurological Examination and Case Recording. 1946.

Donaldson, J. K.: Surgical Disorders of the Chest. Second edition. 1947.

Gifford, S. R.: Handbook of Ocular Therapeutics. Fourth edition revised by D. Vail. 1947.

Gilberg, A.: Eskimo Doctor. 1948.

Graves, C.: The Story of St. Thomas's, 1106-1947. 1947.

Hale-White, W.: Materia Medica. Twenty-seventh edition revised by A. H. Douthwaite. 1947.

Harris, D. T.: Practical Histology for Medical Students. Fourth edition. 1947.

Hill, H.: Pasteurization. Second edition. 1947.

Ikin, A. E., and Oates, G. E.: A General Course in Hygiene. Third edition revised by H. A. Nathan. 1947.

Keller, L.: Índice Bibliográfico de Lepria. Vol. 2. 1947.

Knudsen, K. A.: Textbook of Gymnastics. Second edition, vol. 1. 1947.

Lewin, P.: The Foot and Ankle. Third edition. 1947.

Lickley, J. D.: An Introduction to Gastro-enterology. 1947.

McAllister, J. B.: Ethics, with special application to the nursing profession. 1947.

McCormick, C. O.: Textbook on Pathology of Labor, the Puerperium and the Newborn. Second edition. 1947.

Neustatter, W. L.: Modern Psychiatry in Practice. Second edition. 1948.

New York Academy of Medicine: Medicine in the Changing Order. 1947.

Parsons, Sir J. H., and Duke-Elder, Sir S.: Diseases of the Eye. Eleventh edition. 1948.

Peterson, D., and Smith, J. F.: Modern Methods of Feeding in Infancy and Childhood. Ninth edition. 1947.

Romanis, W. H. C., and Mitchiner, P. H.: Science and Practice of Surgery. Eighth edition, two vols. 1948.

Ryle, J. A.: The Natural History of Disease. Second edition. 1948.

Sammarino, E. S.: Tratado Practico de Hemoterapia. 1947.

Stokvis, B.: Psychologie der Suggestie en Autosuggestie. 1947.

Tetau, J.: Homöopathie. Second edition revised by L. A. Rousseau and H. Deroche. 1947.

Tredgold, A. F.: Textbook of Mental Deficiency (Amentia). Seventh edition. 1947.

Troup, W. A.: Therapeutic Uses of Infra-red Rays. Fourth edition. 1947.

Vallejo, E. A.: Disfunciones Motoras del Estomago. 1947.

RETURN TO PRACTICE

The Central Medical War Committee announces that Dr. Clifford G. Parsons, F.R.C.P., has resumed civilian practice at 89, Harborne Road, Edgbaston, Birmingham.

Association Notices

SIR CHARLES HASTINGS CLINICAL PRIZE

The Sir Charles Hastings Clinical Prize, which consists of a certificate and a money award of 50 guineas, is again open for competition. The following are the regulations governing the award:

1. The prize is established by the Council of the British Medical Association for the promotion of systematic observation, research, and record in general practice; it includes a money award of the value of 50 guineas.

2. Any member of the Association who is engaged in general practice is eligible to compete for the prize.

3. The work submitted must include personal observations and experiences collected by the candidate in general practice, and a high order of excellence will be required. If no essay entered is of sufficient merit no award will be made. It is to be noted that candidates in their entries should confine their attention to their own observations in practice rather than to comments on previously published work on the subject, though reference to current literature should not be omitted when it bears directly on their results, their interpretations, and their conclusions.

4. Essays, or whatever form the candidate desires his work to take, must be sent to the British Medical Association House, Tavistock Square, London, W.C.1, not later than Dec. 31, 1948. The prize will be awarded at the Annual General Meeting of the Association to be held in 1949.

5. No study or essay that has been published in the medical press or elsewhere will be considered eligible for the prize, and a contribution offered in one year cannot be accepted in any subsequent year unless it includes evidence of further work. A prize-winner in any year is not eligible for a second award of the prize.

6. If any question arises in reference to the eligibility of the candidate or the admissibility of his or her essay the decision of the Council on any such point shall be final.

Each essay must be typewritten or printed, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto, and enclosing the candidate's name and address.

The writer of the essay to whom the prize is awarded may, on the initiative of the Science Committee, be requested to prepare a paper on the subject for publication in the *British Medical Journal* or for presentation to the appropriate Section of the Annual Meeting of the Association.

Inquiries relative to the prize should be addressed to the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1.

KATHERINE BISHOP HARMAN PRIZE

The Council of the B.M.A. is prepared to consider an award of the Katherine Bishop Harman Prize of the value of £75 in 1949. The purpose of the prize, which was founded in 1926, is to encourage study and research directed to the diminution and avoidance of the risks to health and life that are apt to arise in pregnancy and child-bearing. It will be awarded for the best essay submitted in open competition, competitors being left free to select the work they wish to present, provided this falls within the scope of the prize. Any medical practitioner registered in the British Empire is eligible to compete.

Should the Council of the Association decide that no essay submitted is of sufficient merit, the prize will not be awarded in 1949, but will be offered again in the year next following this decision, and in this event the money value of the prize on the occasion in question will be such proportion of the accumulated income as the Council shall determine.

The decision of the Council will be final.

The essay must be typewritten or printed in the English language, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address. Essays must be forwarded so as to reach the Secretary, to whom all inquiries should be addressed, B.M.A. House, Tavistock Square, London, W.C.1, not later than Dec. 31, 1948.

MIDDLEMORE PRIZE

The Middlemore Prize consists of a cheque for £50 and an engraved certificate, and was founded in 1890 by the late Mr. J. H. Middlemore, F.R.C.S., of Birmingham, to be awarded to the author of any work on any subject which the Council of the Association may from time to time select in connection with the study of medicine or surgery. The Council of the Association has decided that the prize in the year 1949 shall be awarded for work on "The Value of Orthopaedics in

the Treatment of Squint." Essays submitted in competition must reach the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1, on or before Dec. 31, 1948. Each essay must be signed with a motto and accompanied by a sealed envelope marked on the outside with the motto and containing the name and address of the author. In the event of no essay being of sufficient merit the prize will not be awarded in 1949.

PRIZES FOR NURSES

The Council of the British Medical Association is prepared to consider the first award in 1948 of three prizes each of the value of 20 guineas for the best essay and three prizes each of the value of 10 guineas for the second best essay submitted in open competition by each of the following categories of nurses: (i) Pupil nurses; (ii) State registered nurses working in a hospital; (iii) State registered nurses not working in a hospital—i.e., district nurses, private nurses, etc.

The subjects of the essays for 1948 shall be: Category (i) "Suggested Improvements in the Methods of Training Nurses"; Category (ii) "Nursing the Patient, not the Disease: the Nurse-Patient Relationship"; Category (iii) "Difficulties of Nursing in the Patient's own Home and their Solution."

The purpose of these prizes is the promotion of systematic observation among nurses. In awarding the prizes due regard will be given to evidence of personal observation. No essay that has previously appeared in the medical press or elsewhere will be considered eligible for a prize. Nurses who are undergoing a course of training at a hospital are eligible to compete under category (i); nurses registered by the General Nursing Council are eligible to compete under categories (ii) and (iii). If any question arises in reference to the eligibility of a candidate or the admissibility of his or her essay, the decision of the Council of the British Medical Association shall be final. Should the Council decide that no essay entered is of sufficient merit, no award shall be made. Each essay must be typewritten or legibly written, must be unsigned, and have attached to it a sealed envelope containing the name and address of the candidate and the category into which he or she falls. Essays must be forwarded so as to reach the Secretary of the British Medical Association not later than May 31, 1948. Inquiries about the prizes should be addressed to the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1.

CHARLES HILL,
Secretary.

GROUP OF VENEREOLOGISTS

A meeting of the recently formed Group of Venereologists will be held at B.M.A. House, Tavistock Square, London, W.C.1, on Friday, May 7, 1948, at 2 p.m.

The Group consists of all those members of the Association who are engaged predominantly in the practice of venereology. The agenda will consist of (a) the election of a chairman; (b) consideration of the size and constitution of the Group Committee; and (c) a general discussion on the work of the Group.

CHARLES HILL,
Secretary.

Diary of Central Meetings

MAY

5. Wed. Council, 11 a.m.

Branch and Division Meetings to be Held

METROPOLITAN COUNTIES BRANCH.—At B.M.A. House, Tavistock Square, London, W.C., Tuesday, June 1, 2.30 p.m. Ninetieth Annual General Meeting. Agenda: Report of Branch Council for 1947-8; report of Branch representatives on Central Council, 1947-8; election of officers for 1948-9; address by incoming President.

Meetings of Branches and Divisions

COVENTRY DIVISION

A joint meeting of the Coventry and the Nuneaton and Tamworth Divisions was held in the Coventry and Warwickshire Hospital on April 13. The meeting was the occasion of a visit to the Divisions of the Clinical and Pathological Section of the B.M.A., Birmingham Branch. Cases were demonstrated by Prof. A. P. Thomson, Prof. K. D. Wilkinson, Mr. Hugh Donovan, Mr. J. L. Collis, and Mr. Nisbett, to all of whom an enthusiastic vote of thanks was approved on the motion of Dr. Murray Bladon, of Coventry, seconded by Dr. Procter, of Atherstone.

The address of the North-west Metropolitan Regional Hospital Board is 11a, Portland Place, London, W.1 (Tel.: Museum 9575/9).

HISTAMINE*

BY

J. H. GADDUM, Sc.D., F.R.S.

Professor of Materia Medica and Pharmacology, University of Edinburgh

(From the Department of Pharmacology, University of Edinburgh)

Histamine has attracted much attention because it has dramatic pharmacological effects in very small doses and because it is widely distributed in animal tissues. These two fundamental facts were clearly established by Dale and his colleagues between 1910 and 1927. This early work has often been reviewed (Feldberg and Schilf, 1930; Gaddum, 1936, etc.) and will only be briefly summarized now.

Pharmacological Actions

Histamine causes contraction of most plain muscle. This effect is particularly marked if the muscle comes from a guinea-pig: and this animal provides various preparations which can be used to detect histamine in concentrations down to about 10^{-7} or 10^{-8} . If a high concentration is left in contact with the muscle the contraction is not maintained. The muscle relaxes, although still in contact with histamine; even after the solution has been changed the muscle remains for a time insensitive to further applications of histamine though still sensitive to other drugs.

The contraction of plain muscle is well shown in isolated preparations and also when histamine is injected intravenously. In some species of animals large doses kill by this action, but the form of death varies, probably owing to differences in the distribution of the plain muscle. Guinea-pigs are killed by the action of histamine on the bronchi; rabbits by its action on the pulmonary arteries; and dogs by its action on the hepatic veins.

In some animals, including cats and men, histamine has a powerful action on the capillaries, which dilate. This is well shown by injecting histamine into skin, when it produces the well-known triple response which is called urticaria because of its resemblance to the effects produced by the sting of a nettle. The simple explanation of this resemblance has recently been discovered by Emmelin and Feldberg (1947), who find that nettle-stings actually contain histamine in a concentration of about 0.1% together with acetylcholine in a concentration of 1%. The urticaria is due to the histamine, and the pain is due to the two drugs acting together. The intradermal injection of either of them alone is painless.

When large doses of histamine are injected intravenously in cats the capillaries dilate so much that the blood pressure falls to very low levels, and so much plasma leaks out that the blood becomes very concentrated. These changes are the cause of death in cats. Histamine thus causes a form of shock which has much in common with shock due to other causes. The enthusiasts concluded that

shock was always due to the release of histamine, but they were certainly wrong; there are many kinds of shock.

When histamine is injected subcutaneously, so that it is slowly absorbed, the mucous membrane of the stomach secretes large quantities of acid juice poor in enzymes. The use of this fact as a test of gastric function is the main clinical application of histamine. Histamine also stimulates the lacrimal glands, the salivary glands, the pancreas, and the glands of the intestine, but not the sweat glands.

Histamine is a base (β -iminazoleylethylamine) which can be obtained from histidine by decarboxylation. It is soluble in water and ethyl alcohol, but not in ether. It can be extracted from alkaline watery solutions by various solvents such as amyl alcohol and re-extracted from the amyl alcohol with acid. It is extremely stable in acid solution. When titrated with acids it shows two dissociation constants corresponding to pH 5.9 and pH 9.7 (Levy, 1935). Under physiological conditions it therefore behaves as a univalent cation. According to Niemann and Hays (1942) the structure of this cation is as shown above. Ionization is associated with the uptake of a proton attached to the amine group by means of a hydrogen bond (shown by dotted line) and chelation occurs, which means that an unstable ring is formed.

*A special lecture given at the University of London on Feb. 20.

Histamine may be adsorbed in two different ways (see diagram). Adsorption on charcoal is increased when the solution is alkaline; this is presumably because charcoal adsorbs the free base (Phelps and Peters, 1929). On the

Diagram showing adsorption of histamine. In alkaline solutions adsorption on charcoal is increased, but adsorption on fuller's earth or magnesium trisilicate is decreased.

other hand, adsorption on fuller's earth or magnesium trisilicate is increased when the solution is acid; this is presumably because these substances adsorb histamine ions in exchange for other cations.

Several workers have studied the pharmacological activity of methylhistamines. Vartiainen (1935) found that if one methyl group is attached to the amino-nitrogen the resulting compound is more active than histamine in some tests and less active in others. If two methyl groups are attached to this group the compound still has histamine activity, but is less active. If three methyl groups are attached the compound becomes a quaternary base which acts like nicotine and has no histamine activity. Alles, Wisegarver, and Shull (1942) studied the compound formed by attaching a methyl group in position α . This compound has very little histamine activity; the most interesting thing about it is that it is not attacked by the enzyme histaminase (or diaminoxidase). They point out that this effect is similar to that of attaching a methyl group in the corresponding position in sympathomimetic amines, which are thus protected against aminoxidase.

There are three possible pyridylethylamines, depending on the position of the side-chain in the pyridine ring. The compound whose formula is shown above (2-pyridylethylamine) has effects like those of histamine and is almost as active. It is therefore suggested that the essential group for histamine activity is that shown above [$\text{CH}_2\text{NC}(\text{CH}_3)_2$]. The other two pyridylethylamines do not contain this group and do not act like histamine. Their pharmacological effects are like those of sympathomimetic amines, whose essential structure is phenylethylamine. In these compounds the pyridine ring behaves as if it were a benzene ring (Walter, Hunt, and Fosbinder, 1941; Niemann and Hays, 1942).

Antihistamines

(Bovet and Walther, 1944; Feinberg, 1946; Jew, 1947). It has long been known that many of the pharmacological effects of adrenaline are opposed to those of histamine. These two substances act as physiological antagonists, and the others as such. The injection of histamine releases adrenaline and, according to Staub (1937), the injection of adrenaline releases histamine. He found that, when 0.2 mg. of adrenaline was injected intravenously in man in nine cases, the plasma histamine rose from 10 to 50 mg. per litre. This work seems to confirm a theory put forward by Dale, who thought

that the vasodilator effect of small doses of adrenaline might be due to release of histamine. Experiments which appeared to show that adrenaline did release histamine from the lungs turned out to be inconclusive (Dale and Richards, 1927), but the work of Staub supports the theory on which the experiments were based.

Another class of substance which is opposed to histamine comprises the substances that destroy it. Formaldehyde (Kendall, 1927) destroys histamine *in vitro* and may oppose its actions on an isolated organ. According to Garan (1938) CO_2 has a similar action, possibly due to the formation of a carbamino compound. Nitrites also destroy histamine *in vitro* (Gaddum and Schild, 1934). There is no evidence that they do this *in vivo*; if there were, it might explain the fact that nitrites inhibit smooth muscle. The enzyme histaminase is presumably the main factor which does destroy histamine in the body; but it seems to be ineffective when injected, and it is difficult to see how it can possibly be effective by the mouth (cf. Feinberg, 1946).

It is possible to immunize the body against histamine by injecting an antigen prepared by coupling histamine to a protein (cf. Feinberg, 1946). This discovery would have made more sense than it did if it had not been overshadowed by the discovery of drugs which probably act as competitive antagonists, combining with the tissues in the same way as histamine and keeping the histamine off.

Perhaps the first competitive antagonist that should be considered is histamine itself. Its power of desensitizing tissues to its own action has already been mentioned. In the search for other antihistamines Edlbacher, Jucker, and Baur (1937) tested most of the amino-acids and found that histidine, arginine, and cysteine had some effect on high concentrations. It seems natural that histidine should act in this way as its molecule differs from that of histamine only by the presence of a carboxyl group. The molecule of arginine can be drawn to look like that of histamine, but it is not so easy to suggest why cysteine should act in this way.

The discovery of the really potent antihistamines is mainly due to Bovet and his colleagues in the Pasteur Institute in Paris. This laboratory had been interested for some years in a series of drugs with an action antagonistic to adrenaline (Bovet, 1943). The molecules of adrenaline and its allies contain phenylethylamine. The anti-adrenalines studied in Paris were tertiary amines containing phenoxyethylamine. The introduction of oxygen between the benzene ring and the side-chain, together with the attachment of alkyl groups to the amino-nitrogen, seemed to convert drugs which acted like adrenaline into drugs which opposed adrenaline. Ungar, Parrot, and Bovet (1937) found that some of these drugs also acted against histamine. The first of the new antihistamines to attract attention was 929F, or thymoxyethyldiethylamine (Bovet and Staub, 1937). The more active drugs discovered later were mostly modifications of this original substance. The formulae of some of these substances are here shown.

In 1571F (Staub, 1939) the oxygen in 929F is replaced by NC_2H_5 and thymol by phenol. In "antergan" (Halpern, 1942) the NC_2H_5 is replaced by $\text{N}(\text{CH}_2\text{C}_6\text{H}_5)_2$ and the diethylamine group is replaced by dimethylamine. In "neantergan" (Bovet *et al.*, 1944) the benzene ring is replaced by pyridine, and a methoxy group appears. This interesting drug is also known as pyranisamine or "anthisan." "Pyribenzamine" has just the same molecule as neantergan except for the absence of the methoxy group.

A large number of other antihistamines have been synthesized in the last few years, including benadryl, "antistin," chlorothen, RP 3277, hetramine, and others, but neantergan appears to be more active and specific than most of the other antihistamines which have been discovered more recently.

Various theories have been advanced to explain the action of these drugs, but the most probable is that they act by competition, blocking up the sites of action of histamine. The results of quantitative studies of the antagonism are compatible with this view. The slope of the logarithm of the dose-effect curve appears to be unaltered by antihistamines (Schild, 1947b). The antagonism between benadryl and histamine seems to be simple (Wells *et al.*, 1945). Halpern and Mauric (1946) have studied the antagonism between antergan and histamine and got more complex curves, but their results can be fitted by a formula of the type proposed by A. J. Clark (1937) to express the relationship in the case of other drugs which are thought to act by competition.

Bovet believes that not only the antihistamines but anti-adrenals such as phenoxymethyldiethylamine act in this way. It has been objected (Loew, 1947) that the molecules of antihistamines are so different from those of histamine and from one another that they would not be expected to combine with the same groups in tissues. The manner in which the above formulae are drawn represents an attempt to answer to this objection. It has already been concluded from the study of the pyridylethylamines that the essential pharmacodynamic group of histamine is the skeleton shown in thick lines in its formula. Neantergan contains this skeleton, but the two parts of it are separated by a nitrogen atom with other groups attached to it. This separation of the side-chain from the ring is comparable with the similar separation in the molecules of the synthetic anti-adrenals. It is noteworthy that the nitrogen in the ring in neantergan is in the same position as it is in histamine. Several other powerful antihistamines, such as pyribenzamine, hetramine, and chlorothen, contain a nitrogen in the same position. Some of the other molecules do not fit into this picture quite so well, but none of them are so widely different from neantergan as to disprove the theory of competitive antagonism. This is not, however, the only possible theory.

These antihistamines appear to antagonize all the actions of histamine, with the notable exception of its action on the gastric juice, which is little, if at all, affected. Their activities have been measured in various ways, the most satisfactory being probably that proposed by Schild (1947a), according to which the activity is expressed in terms of the pA_{50} —the negative logarithm of the molar concentration which is just sufficient to make the tissue half as sensitive to histamine as it was before. Using guinea-pig's intestine, Schild measured the pA_{50} for neantergan, benadryl, pethidine, and atropine acting against both histamine and acetylcholine. Reuse (1948) has confirmed Schild's results for neantergan and also obtained estimates for antergan, antistin, and RP 3277. These results agree with those of other workers obtained by different methods in showing the outstanding activity and specificity of neantergan. Most of the antihistamines are fairly powerful antagonists for acetylcholine; many of them have a local anaesthetic effect and mixed effects on the central nervous system, which is depressed in man but excited in most other animals (Loew, 1947).

Other substances found to have some antihistamine action include peptamines containing histamine (Rocha e Silva, 1943), iminazole (Morris and Dragstedt, 1945), picrotoxin (Anrep *et al.*, 1939), and nicotinamide (Halpern and Dainow, 1944).

Antihistamines can provide evidence for or against theories which attribute physiological changes to the liberation of histamine. Such evidence is of real value only when one of the

more specific drugs such as neantergan is used. Experiments of this type support the view that many of the phenomena of anaphylaxis are due to the release of histamine. On the other hand, benadryl has been found ineffective in protecting animals against trypsin (cf. Loew, 1947). This does not invalidate the evidence that trypsin liberates histamine, but does suggest that its actions are not all due to the release of histamine.

The Estimation of Histamine

Practically all our knowledge of the behaviour of histamine in the body is based upon biological assays. Colorimetric methods have been devised, but they have been found to be comparatively laborious, insensitive, and unspecific. In the early work histamine was generally detected by its effect on the cat's blood pressure, but the favourite test to-day depends on the guinea-pig's intestine. Other suitable tissues are the guinea-pig's uterus or bronchi, the hen's rectal caecum, and the human skin. In all such tests the extract of the tissue is compared with a solution of histamine and the doses adjusted until the two solutions cause equal effects. For really accurate assays the size of the effects can be measured and the result calculated statistically (Schild, 1942).

Crude tissue extracts contain many pharmacologically active substances besides histamine, and when such extracts are used the result means very little. At one time it was customary to use such extracts and to speak vaguely of histamine-like substances. The introduction of improved pharmacological techniques has made these tests more specific, and if proper precautions are taken it is now possible to be reasonably certain that the result of an assay does give an estimate of the concentration of histamine itself.

In order to do this it is necessary to subject the extract to chemical or physical procedures which remove or destroy all other substances that would affect the test. The estimation is thus comparable with a colorimetric estimation in which tissues are ashed or extracted before the final test is applied. In a method which Barsoum and I (1935a) devised in Cairo for the assay of histamine the tissue is minced and extracted with trichloroacetic acid, which precipitates the proteins. The trichloroacetic acid is removed from the extract with ether, and strong hydrochloric acid is then added and the mixture boiled for 1½ hours. This destroys other substances, and generally gives a pharmacologically pure solution after the HCl has been evaporated off. This extract is tested in comparison with histamine on guinea-pig's ileum. We found that when the concentration of histamine was very low there was enough potassium in this final solution to interfere with the test, so we devised a technique involving alcoholic extraction to get rid of this potassium when necessary. Code (1937a) improved this method by the discovery that extraction with ether was unnecessary because the HCl destroyed the trichloroacetic acid. Since then various other methods of extracting histamine for pharmacological tests have been used (cf. Minard, 1940; McIntire *et al.*, 1947).

By such methods it is generally possible to obtain pharmacologically pure extracts, but until confirmatory tests are made it is unsafe to assume that this result has been achieved. The best confirmatory test is to make parallel quantitative assays. The extract is compared quantitatively with histamine by several different methods. If all the results agree quantitatively it is probable that they give an estimate of histamine (cf. Chang and Gaddum, 1933). Histamine can be distinguished from N-methyl histamine in this way; the methods used so far would not distinguish it from N-dimethyl-histamine.

The effects of antihistamines can also be used in evidence, provided that the experiment is properly designed

Large amounts of antihistamines will desensitize tissues not only to histamine but also to other substances such as acetylcholine and potassium. The effect of antihistamines is therefore convincing only when they antagonize extracts in the same concentrations that they antagonize histamine. One sound way of arranging the experiment is to obtain a series of equal responses of the guinea-pig's gut with the extract and with histamine given in alternate doses. A small concentration of neoantergan is then added to the bath for a minute and the alternate dosing continued. The result is that the response to histamine is greatly depressed or abolished and then gradually recovers as successive doses are given. If the active principle in the extract is histamine its effects will be depressed to the same extent and for the same time as the effects of the standard solution of histamine. This type of test can be used to distinguish histamine from many substances, but Schild (1947b) has shown that it does not distinguish histamine from N-methyl-histamine, although these two substances can be differentiated by the method of parallel quantitative assays. This result suggests that antagonists can be used to distinguish between drugs acting at different sites in tissues but not between two drugs which act at the same site.

Evidence for the identification of histamine in extracts can also be obtained by exposing the extracts to various solvents, and destructive agents such as histaminase; but it must be remembered that this enzyme has not been prepared in the pure state, and that preparations containing it may contain other enzymes as well. Evidence depending on the use of this enzyme is not conclusive by itself.

Behaviour of Histamine in the Body

It seems likely that the histamine in the body is derived originally from histidine by decarboxylation. Histidine is one of the essential amino-acids, and it is generally supposed that the iminazole group which it contains is not synthesized in the animal body but absorbed from the intestine. Histidine may be converted into histamine by bacteria either in the food before it is eaten or possibly in the intestine. When animal tissues are eaten they also often contain histamine derived from the animal. Histamine is absorbed by the mucous membrane in the mouth, but most absorption occurs in the ileum. However, large doses may be eaten with surprisingly little effect, for reasons to be discussed later.

Histamine may also be formed from histidine in the body by the enzyme histidine decarboxylase (see Blaschko, 1945), which is present in the liver and kidneys of certain small animals. It is not known what proportion of the histamine normally present in the body is derived from this source and what proportion is absorbed from the intestine, but the fact that histidine decarboxylase appears to be absent in many species of animal suggests that it does not play an important part in providing the body with histamine.

Numerous estimates have been made of the amounts of histamine in animal tissues, with varying results (Feldberg and Schiff, 1930; Gaddum, 1936; Rocha e Silva, 1946; etc.). There are usually particularly large amounts in the lungs and skin, but most tissues may contain quite large amounts in some species at some times. The blood has attracted particular attention because it is easy to obtain successive samples of it. Most of the blood histamine is in the cells. The plasma usually contains so little that it is difficult to estimate it, but some does seem to be there in a pharmacologically active form. Emmelin (1945), for example, took pairs of guinea-pigs of which one normally had a high concentration of histamine in its plasma and the other a low concentration. When he established a cross-reaction between two such guinea-pigs bronchoconstriction occurred in the animal with an initial low plasma

histamine and not in the other animal. This experiment seems to show that the concentration in the plasma does play a part in regulating the normal functions of the body. Code (1937b) came to the conclusion that most of the blood histamine is in the granulocyte cells. This view was confirmed by the fact that in myeloid leukaemia when the number of granulocyte cells was very high the blood histamine reached astronomical proportions. Later work suggests that this is not true of all species of animal and that most of the histamine in rabbit's blood is in the platelets (Minard, 1940). In any case, estimations of total blood histamine are often difficult to interpret; a fall of blood histamine may be due to the disappearance or destruction of histamine-containing cells.

Observations on the blood histamine are also complicated by the fact that when histamine is liberated into the blood by one organ it may be rapidly absorbed, destroyed, or excreted by another. Anaphylaxis in rabbits causes a fall in the histamine content of the lungs, spleen, and blood, and it is not known what happens to the histamine in these circumstances. The injection of histamine itself in rabbits has been found to cause a fall in the blood histamine apparently due to the loss of leucocytes or platelets (Rose and Browne, 1941). Such observations help to explain why estimations of histamine in the blood have not led to as rapid advances in the study of histamine as seemed possible at one time.

It has long been obvious that the histamine in the tissues cannot all be free; something prevents it acting under normal conditions. If all the histamine in a cat's lungs were liberated it would kill the cat. The methods generally used for the estimation of histamine do not estimate free active histamine but only the total amount that can be extracted from the tissues. When tissues are ground up in saline part of the histamine is released, but part of it appears to be bound to cellular debris, from which it can be released by procedures, such as heat, which coagulate the proteins (Trethewie, 1938).

When histamine is injected intravenously most of it disappears from the blood within a minute or two and is taken up by the tissues and particularly by the kidney (Rose and Browne, 1938; and cf. Emmelin, 1945). Various alkaloids disappear from the blood equally quickly. It is unlikely that this phenomenon is entirely due to the combination of the drug with the specific receptors on which it acts. It is thus probable that histamine can combine with tissues in at least two ways, one of which is specific and produces pharmacological effects, and the other of which is unspecific and merely removes the drug from the blood. According to Phelps (1935) the pharmacological effects depend on the combination of free histamine base with the tissues, and according to Rocha e Silva (1946) the unspecific combination of histamine with the tissues depends on a mechanism which will be discussed later. But first consider the factors which release histamine from the tissues.

Release of Histamine from Tissues

A number of different methods have been used to study this question. Lewis (1927) showed that various injurious agents produced effects which could be attributed to the release of histamine or something like histamine. The best-known of these effects is the local triple response produced in the skin by intradermal injections, but Lewis and his co-workers also observed other effects such as vasodilatation in the skin of the face which could be attributed to the release of histamine into the general circulation (Lewis and Harmer, 1927). Various other similar methods have been used; for example, the released histamine has been detected by its effect on the gastric juice (Kalk, 1929;

Ungar, 1935; Feldberg and Holmes, 1941) and on the blood pressure (McIntosh and Paton, 1947).

In some experiments the evidence has been the demonstration of a general rise of the histamine content of the circulating blood (Dragstedt and Mead, 1936) or of the blood coming from one particular organ (Anrep and Barsoum, 1935) or in the lymph (Dragstedt and Gebauer-Füllnegg, 1932). The release of histamine can also be demonstrated in tissues such as guinea-pig's lungs perfused with salt solutions (Bartosch, Feldberg, and Nagel, 1932) or by diffusion from tissues suspended in salt solutions (Schild, 1939) or from blood cells into plasma (Katz, 1940). Another possible method, to be discussed later, depends on estimating histamine in the urine.

The factors which control the release of histamine have recently been reviewed by Kellaway (1947), and it will therefore be unnecessary to discuss all the details here.

Histamine is liberated by trypsin, and this fact has been made the basis of an interesting theory regarding the way in which histamine combines with tissues. Rocha e Silva (1946) showed that crystalline trypsin liberates histamine from lungs or from blood cells. It has been shown by Bergmann that crystalline trypsin is a much more specific enzyme than had been supposed, and that it acts on the peptide links formed by the carboxyl groups of the basic amino-acids lysine and arginine. Rocha e Silva therefore suggests that the amine group in histamine combines with the carboxyl groups in these two acids, which themselves presumably form part of protein molecules in the tissues. In support of this very definite theory he finds that chymotrypsin, which attacks the carboxyl group of aromatic amino-acids, does not liberate histamine from cells. On the other hand, papain, which contains a mixture of proteolytic enzymes, does liberate histamine (Rocha e Silva and Andrade, 1943). There is evidence that proteolytic enzymes are liberated or activated in various forms of injury. This is one mechanism by which histamine may be released.

Rocha e Silva (1946) has suggested a theory of how this happens. It is well known that histamine is released in anaphylactic shock, together with other substances such as heparin (Feldberg, 1941; Dragstedt, 1941; Rose, 1947). At the same time leucocytes and platelets disappear from the blood. Rocha e Silva found that both peptone and extracts of ascaris caused similar effects in dogs, and obtained microscopical evidence that the leucocytes and the platelets were retained in the liver. He believes that these cells liberate or activate trypsin, or some similar enzyme, in the tissues and that this trypsin then liberates both histamine and heparin. Such experiments are complicated by the fact that heparin antagonizes the action of trypsin (Rocha e Silva, 1945).

A large number of other substances are known to liberate histamine, and it is clear that they do not all act in the same way. The effects of various forms of injury have been studied in detail by Feldberg, Kellaway, and their co-workers in Australia (Kellaway, 1947), who found that a number of different irritant poisons had various effects in common. The poisons studied included snake venoms, bee venom, peptone, toxins from *staphylococcus* and *Clostridium welchii*, and mercuric chloride. All these poisons caused a liberation of histamine, and some of them the liberation of other substances as well. For example, cobra venom also liberated adenosine compounds, which inhibit most smooth muscle, and a substance which causes a slow contraction of guinea-pig's isolated intestine and is known simply as the "slow-reacting substance." Another important substance liberated by cobra venom is lysolecithin, which is formed from lecithin by an enzyme. This

substance is itself destructive of cells, causing haemolysis and the release of proteins, pigments, histamine, and small amounts of the slow-reacting substance (Feldberg and Kellaway, 1938). Some, at least, of the release of histamine by cobra venom must be the secondary result of the formation of lysolecithin.

Histamine is also liberated by various substances which do not produce obvious injury. For example, Alam *et al.* (1939) showed that curare liberates histamine, and this fact has been confirmed in experiments with tubocurarine (Schild and Gregory, 1947; Grob *et al.*, 1947). McIntosh and Paton (1947) have also found that stilbamidine and a series of other diamidines as well as diamines and diguanidines also release histamine in the body.

In most of the experiments discussed so far there was no question of any new formation of histamine. The appearance of histamine in the fluids in contact with tissues has often been shown to be accompanied by a disappearance of similar amounts of histamine from the tissues themselves. The work of Dekanski (1945) suggests that some other mechanism may play a part in the effects of the exposure of tissues to high temperatures. In the hope of following the fate of histamine liberated by injury he made extracts of whole mice. Anaesthetized mice were immersed in water at 60° C. for 10 or 30 seconds. During the first hour after this treatment the total amount of histamine which could be extracted from the whole body rose from an average value of 216 µg. per mouse to about double this value. The main site of this new formation of histamine appeared to be the skin, but it is not known from what precursors the histamine was formed.

The Fate of Histamine

Histamine is destroyed by some bacteria and also by the enzyme histaminase which is present in the body (Best, 1929). According to Zeller (1938, 1941) this same enzyme also destroys various diamines, such as putrescine and cadaverine, and should therefore be called diaminoxidase. The enzyme is inhibited by cyanide and acts by oxidation. One atom of oxygen is absorbed and one molecule of ammonia is formed when one molecule of histamine is destroyed by the purified enzyme; H_2O_2 is formed and the iminazole ring is destroyed. The most sensitive method of estimating the amount of enzyme in a solution depends on adding histamine and following its destruction by pharmacological tests. Other methods depend on the measurement of the oxygen consumption, the ammonia production, and the peroxide production.

The highest concentrations of the enzyme are in the intestinal mucous membrane, the kidney, and the placenta. The liver contains surprisingly little. In normal circumstances the blood contains very little, but during pregnancy there is an enormous increase of the histaminase content of the blood of women. This phenomenon was first described by Marcou (1937) and has been confirmed by many others (for references see Ahlmark, 1944; Anrep *et al.*, 1947). The enzyme is thought to come from the placenta.

Kapeller-Adler (1944) studied this phenomenon by means of a colour test depending on the formation of H_2O_2 . The rise in the concentration of the enzyme in the blood during normal pregnancy could be demonstrated by this test when either histamine or cadaverine was used as substrate, but bloods taken from women suffering from eclampsia or pre-eclamptic toxæmia behaved in a curious way. The effect of these bloods on cadaverine was similar to that of blood from normal pregnant women, but their effect on histamine was much less. This observation seemed at first to suggest that the enzyme oxidizing cadaverine was

not, after all, identical with the enzyme oxidizing histamine. The evidence on this point has therefore been re-examined using the Warburg technique to measure the oxygen consumption as well as other tests. A highly purified preparation of the enzyme from pig's kidney was used in this work. The results showed that there were not two independent enzymes. When histamine and cadaverine were both present the combined effect on the oxygen consumption was less than the sum of their effects when either is present without the other. Cadaverine inhibited the destruction of histamine as measured by biological assay. The effects of various poisons and changes of pH produced similar effects with either substrate, but dialysis had an effect like eclampsia: it decreased the action of the purified enzyme on histamine and increased its action on cadaverine. Both these effects were reversed by flavine adenine dinucleotide; the effect of dialysis thus appears to be due to the removal of this substance. The relation of these observations to those on toxæmia obviously requires further investigation.

The eventual fate of most of the histamine in the body is probably to be destroyed by the enzyme histaminase, but a certain amount appears in the urine. The first clear quantitative evidence of this was obtained by Anrep, Ayadi, Barsoum, Smith, and Talaat (1944), who found that the activity of extracts of urine could be increased by acid hydrolysis. The histamine in the urine seems to be partly free and partly conjugated with other substances, from which it can be liberated by acid. These facts have been confirmed and extended in Edinburgh by Adam. He has been using a simplified form of the test devised by Anrep *et al.* to measure the histamine in human urine. In normal circumstances the concentration of histamine in the urine is comparable with that in the blood—about 50 µg. per litre. This is near the limit of what can be measured by the methods available. When histamine is given by the mouth to man about 1% of it appears as conjugated histamine in the urine, but when histamine is given by slow intravenous infusion it is free histamine which appears in the urine. These observations confirm results obtained by Anrep *et al.* in experiments on dogs.

The fact that large doses of histamine have very little pharmacological effect when swallowed may be partly due to this formation of conjugated histamine, but other factors may be more important. The mucous membrane of the gut contains particularly large amounts of histaminase, and this probably also plays a prominent part in protecting the body from the effects of the absorption of histamine. It has already been mentioned that other organs, such as the kidney, also contain histaminase, and the general result is that only a small amount of histamine normally appears in the urine. This proportion may be much greater when large doses of histamine are given. This is well shown in some experiments by Alexander (1944), who injected 3 mg. of histamine intravenously into each of a group of mice, and then followed its fate by estimating it in the urine and in extracts of the whole mouse. The percentage appearing in the urine in these experiments varied widely, but on the average it was 37.7. After 24 hours the histamine content of the mice had fallen practically to the normal value of 0.3 mg. per mouse, so that the other 62.3% of the histamine must have been destroyed in this time. During the first hour, when the mice were flooded with histamine, excretion in the urine was the main channel by which they got rid of it.

The main interest of estimations of histamine in the urine lies in the fact that they provide a possible means of studying the factors which cause the liberation of histamine from the body. Under the conditions of Adam's experiments

there was no detectable rise in the blood histamine, although measurable quantities of histamine appeared in the urine. It thus seems likely that the liberation of histamine in the body may be followed by estimating it in the urine even when no changes occur in the blood histamine.

Histamine in Normal Physiology

It is natural to suppose that the local control of the circulation may depend on histamine. Vasodilatation is known to occur when the blood supply to a tissue is obstructed or when the activity of the tissue is increased. These phenomena may be partly due to the local release of histamine, but the evidence is conflicting. Workers in Cairo got evidence of an increase in the histamine content of blood coming from the voluntary muscles of a dog when the circulation was obstructed; when the muscles were stimulated the effect was much larger. They also did experiments with a heart-lung preparation, and found that when the heart worked harder it liberated more histamine (Barsoum and Gaddum, 1935b; Anrep and Barsoum, 1935; Anrep, Barsoum, and Talaat, 1936; Anrep, Barsoum, Talaat, and Wieninger, 1939). Some of these conclusions were supported by the results of Feldberg and Holmes (1941), who found that stimulation of voluntary muscles caused gastric secretion in cats which could be attributed to the release of histamine. Unfortunately other workers failed to confirm the experiments in Cairo (Code, Lovatt Evans, and Gregory, 1938; Emmelin, Kahlson, and Wicksell, 1941; Kwiatkowski, 1941). Emmelin and Emmelin (1947) found that benadryl in doses sufficient to reduce the effect of histamine did not reduce the reactive dilatation of the vessels in a cat's leg after occlusion of the circulation.

According to Anrep, Barsoum, Salama, and Souidan (1944) some at least of the negative results were due to the fact that the histamine is very rapidly washed away unless drastic measures are taken to control the blood flow when it is first released. It has also been pointed out that the muscles of the dogs in Cairo contained three to four times as much histamine as the muscles of the dogs used by other workers. It is possible that histamine did contribute to the hyperaemia in all the experiments, but that it was only when it was present in large amounts that it appeared in the venous blood. In any case the evidence in favour of histamine's function in the local control of the circulation cannot be regarded with complete satisfaction at present. It is very probable that various other substances are involved.

The question of the release of histamine by nerves has received less attention than it deserves. Ungar (1935) stimulated the posterior roots antidromically in dogs and found that the vasodilatation thus produced was accompanied by gastric secretion. He attributed this at first to the release of histamine into the general circulation, and suggested that these nerves should be called histaminergic. Kwiatkowski (1943) obtained more direct and convincing evidence in favour of this conclusion. He found that antidromic stimulation in cats caused the appearance of a histamine-like substance in the venous blood. Confirmatory results were obtained when a cat's leg was perfused with Tyrode's solution. High concentrations of histamine were also found in extracts of the nerves which cause these effects, and Kwiatkowski considered that this was analogous to the fact that extracts of cholinergic and adrenergic nerves contain high concentrations of the substances liberated at their endings. There are, however, various complications which suggest that the analogy is not a close one. Kwiatkowski himself found that degeneration caused

an increase in the histamine content of nerves, whereas it is known to have the opposite effect on their content of acetylcholine and sympathin. The work of Koshtojanz, Ryvkina, and Mitropolitanskaya (1945) indicates a more complicated situation. They compared the effects of a blow on the head with those of ether narcosis. Extracts of nerves taken from animals killed by this form of violence contained little or no histamine, whereas those obtained from anaesthetized animals contained large amounts. It is clear that there is still much to be learned about the histamine metabolism of nerves.

Therapeutic Applications

(Rose, 1947)

The realization that the release of histamine plays a part in various pathological conditions has stimulated the search for ways of counteracting its effects. The results of this search have already been briefly discussed; the most promising antidotes for histamine are the drugs, like neoantergan, which probably act as competitive antagonists. Their effect in anaphylaxis has led to their clinical use in allergy. They have been found effective in allergic urticaria. In various other dermatological conditions their main effect is to diminish itching. They are also effective in hay-fever and other forms of spasmodic rhinitis. There is evidence that when patients are specifically sensitive to drugs such as liver extracts or insulin the unpleasant effects can be suppressed with antihistamines and the treatment continued. Under these conditions the patient may be desensitized so that the administration of the antihistamine need not be continued indefinitely. Antihistamines may cause various toxic effects, of which the most troublesome at present seems to be drowsiness. Much work remains to be done before the full possibilities and limitations of these drugs are known, but it is already clear that they have some uses. Histamine thus provides another example of the way in which fundamental discoveries which were originally inspired by unorganized scientific curiosity may bear practical fruit which could not have been foreseen.

A paper entitled "Some Aspects of Physique in Boys and Girls," by R. E. Roper, M.A., M.Ed., has been published (price 2s. 6d., post free) by the Research Board for the Correlation of Medical Science and Physical Education, Apothecaries Hall, Blackfriars Lane, Queen Victoria Street, London, E.C.4. Mr. Roper examined 1,852 children from State schools and day nurseries, a sample which excluded children at special schools. He has tabulated the age, height, weight, and other particulars of the physique and carriage of the children. He recommends that education authorities should consider employing chiropodists to work in schools, that special corrective classes should be available for children with minor defects, that a pair of large mirrors should be provided in all schools, that education authorities should provide travelling x-ray equipment to examine the children's physique, that each school should have a rest room for children with special needs, that physical exercise should not be omitted to provide more time for study when examinations approach, and he advocates fuller co-operation between physical education and the medical profession.

"ANTISTIN" IN DERMATOLOGY

BY

JAMES OVERTON, M.D., B.Sc., M.R.C.P.*Honorary Chief Assistant, Skin Department, Leicester
Royal Infirmary*

Research by K. Miescher and co-workers on antihistamines led to the synthesis of "antistin," a substance which chemically has the formula 2 N-phenyl-N-benzyl-aminomethylimidazoline.

The antistin salts used are all white crystalline powders. The hydrochloride, which is 2% soluble in water, is used in the tablets. The methanesulphonate is readily soluble in water, and is given parenterally. Antistin sulphate has a solubility of about 4% in water, and is employed as a local application to the mucous membrane in hay-fever.

Pharmacology

The pharmacological properties of antistin have been investigated by Meier and Bucher (1946a, 1946b) in the usual animal experiments employed to ascertain the efficacy of this type of drug. Anaphylactic symptoms were entirely prevented by previous medication with antistin in rabbits sensitized to egg albumin; antibody production appeared to be increased when elicited in conjunction with the administration of antistin; addition of antistin to the liquid in which isolated organs were immersed suppressed or prevented anaphylactic contraction (Schulz-Dale's experiment). The antagonism of antistin to histamine was shown in the isolated perfused posterior extremity of the rabbit and in the isolated intestine of the guinea-pig; the fatal consequences from histamine-induced bronchospasm in the guinea-pig were prevented by premedication with antistin. Its toxicity was found to be relatively low, and cumulative action slight. Brack (1946) demonstrated its peripheral action on the vasomotor system in man by the effects of local application in scratch-tests with histamine, diethylmorphine, and simple trauma; he observed suppression of the irritation and a reduction in the size of weal formation. Antistin did not reduce the irritation which followed the application of adrenaline in this scratch-test technique. Staub (1946) found that the temporary increase in the histamine content of the blood in man after the slow intravenous administration of 0.2 mg. of adrenaline was diminished or abolished by the previous administration of antistin.

Clinical Trials

Schindler (1946) attempted a clinical evaluation of antistin in a mixed series of conditions associated with pruritus. Among four patients suffering from jaundice due to infective hepatitis, three were relieved in one to three days, and in one there was no conclusive result. In two patients with carcinoma of the duodenum relief was obtained after two and six days' medication respectively. One patient with uterus of unknown aetiology was free from pruritus after two days' treatment. Senile pruritus was relieved in one patient, but in another, after a temporary relief, the drug proved ineffective. An old man with chronic generalized pruritus experienced relief only after taking antistin tablets. Itching associated with

lymphogranulomata was relieved in one patient, but in another, after an initial period of partial relief, the drug proved useless. Relief was obtained after three days' treatment in a patient suffering from plasmocytoma. In a patient with carcinoma of the pancreas immediate success was followed by subsequent failure. The result of treating one patient with drug-pruritus was unconvincing.

Nine cases of acute urticaria—three of which were due to drugs, two to sera, two to foodstuffs, and one following ultra-violet light therapy—were rapidly relieved by antistin. One patient suffering from recurrent urticaria obtained speedy relief from a relapse, whereas another patient who also suffered from myocardial degeneration experienced little benefit. It proved ineffective for two patients with erythema nodosum.

Schindler found that dosage was purely empirical; he administered up to 300 mg. daily intravenously, intramuscularly, or subcutaneously, and up to 600 mg. by mouth. He tried the effect of a 200-mg. dose intravenously in a normal control. The only ill effect suffered was a sense of warmth in the head, lasting about five minutes. Doses of 300 mg. daily for 10 days in four normal controls did not produce any unpleasant symptoms, nor were the pulse, blood pressure, or respiratory rate affected. Occasionally, when the subcutaneous route was used, a painful nodule persisted for a few days at the site of injection.

Brack (1946) has carried out more extensive trials on about a hundred patients suffering from various skin disorders. Nine patients with acute urticaria and four patients with "cold" urticaria manifested rapid relief. Seven patients with chronic urticaria were improved for long periods after 2 to 3½ weeks' medication. Four patients with nervous pruritus obtained relief, whereas five other patients required ancillary measures to effect improvement. Among 17 patients with neurodermite, 12 enjoyed suppression of irritation without any apparent local change occurring in the lesion. Five patients with prurigo vulgaris were cured. Itching in lichen ruber planus, psoriasis, and after scabies also responded to antistin.

The dosage Brack used was empirical, and varied from 100–200 mg. during the night to 600 mg. by mouth through the day. It was also given by intramuscular or slow intravenous injection in doses up to 100 mg. A few patients experienced transitory faintness or dizziness, but this was avoided by reducing the dosage or retarding the rate of intravenous injection. One patient suffered tetany-like cramp of hands and fingers on doses exceeding 400 mg. daily.

Skouby (1947) treated a group of 43 patients—six with vasomotor rhinitis, 10 with angioneurotic oedema, 15 with urticaria, 12 with asthma. It proved effective in the first three groups only. Thirteen patients suffered from mildly disturbing side-effects, which in seven patients persisted during administration of the drug. Two of the latter preferred to discontinue treatment.

Britton (1947) has used it for 11 patients with urticaria, with some relief in five. Twenty among 54 patients developed unpleasant side-reactions, and in seven they were severe enough to prevent continuation of this mode of treatment. The reactions included nausea (9), drowsiness (4), faintness (3), giddiness (3), headache (2), coughing attacks (2), disorientation (1), depression (1), diarrhoea (1).

Dosage, Mode of Administration, and Control Therapy

The following results are culled from clinical experience with the drug dating from March, 1947. It has been used, mainly in the out-patient department, on some 87 cases. Administration has of necessity been given in the majority of cases by the oral route, occasionally supplemented by intramuscular injection. Dosage has generally been

increased until a therapeutic result was achieved, or toxic symptoms supervened, or a dose of 800 mg. daily had been given.

As a control for the results, the effects of substitution of dummy tablets (suitably flavoured with liq. strychnine, 1/192 gr.) and cessation of therapy were assessed. In addition, in the non-urticarial pruritic syndromes the effect of a potassium bromide sedative tonic mixture was compared with that produced by antistin.

Actinic Dermatitis.—Prolonged observation throughout an exceptionally fine summer, with the use of adequate control therapy, did not provide any clear-cut evidence suggesting clinical improvement on antistin in two patients with this disorder, though the drug was pushed to the limits of tolerance. "Benadryl" in maximum tolerated dosage proved equally ineffective.

Cheirpompholyx.—Three patients with cheirpompholyx of constitutional origin obtained no relief from their irritation on antistin 100 mg. four times a day by mouth. A similar lack of response followed the use of benadryl.

Chronic Constitutional Eczema.—Compared with adequate control measures, 12 out of 13 patients experienced a moderate amount of relief from their pruritus without any change in the progress of the local manifestations being noted. Its effectiveness did not exceed that of 10 gr. (0.65 g.) of potassium bromide thrice daily in mixture form. Seven patients had previously obtained no assessable benefit on the maximum tolerated dosage of benadryl.

Infantile Eczema.—Eight patients, ranging in age from 4 months to 6 years, unfortunately showed no evidence of relief of irritation, or improvement in the local condition. Dosage ranged from 25 mg. four times daily for a 4-months-old infant to 50 mg. four times a day in a 6-year-old child. One child, aged 2, vomited on two occasions when taking 50 mg. thrice daily; there was no recurrence of the vomiting on continuing the same dosage.

Eczematous Conditions with Oedema.—The value of antistin therapy in this group of patients proved more difficult to assess. It would have been preferable to produce a series divided into two comparable groups of patients—one treated by local applications and antistin, and a second by local measures only. Circumstances, and the relatively small number of patients, have not permitted this, but the clinical impression gained was that antistin therapy was a useful adjunct in the treatment of this group. There were nine cases.

Varicose Eczema.—A woman suffered sudden generalization, with marked oedema of face, occlusion of eyes, and very severe pruritus. Antistin was given in 100-mg. doses intramuscularly thrice daily for two days, together with the application of lead lotion to the face and zinc cream to the limbs and trunk. The irritation began to diminish in 8 to 12 hours, and the oedema and symptoms had markedly abated in 24 to 36 hours.

Constitutional Eczema.—Three patients who had suffered during a number of years from recurrent attacks of generalized eczema, with oedema of the face and occasionally the arms, were treated in the above manner. The symptoms began to subside in 12 hours, and the oedema in 24 to 36 hours. One patient stated that on previous occasions the attacks, which were treated by similar local measures only, had persisted for longer periods, the oedema generally requiring from 4 to 7 days to abate and the pruritus continuing for a further number of days.

Contact Dermatitis.—Two men, suffering from mercury and cement contact dermatitis, respectively, with swelling of the face, neck, forearms, and hands, associated with confluent vesicular eczema, showed a great reduction in the oedema, diminution of the irritation, and some regression of the eruption after 36 hours. Antistin was given in a 100-mg. dose intramuscularly thrice daily for one day, followed by 200 mg. by mouth four times a day. Again, simple local applications were concurrently used.

Two other patients suffering from a similar sensitization dermatitis, but of unknown aetiology, involving the face, responded in an equally satisfactory manner.

Erythema Multiforme.—No beneficial effect was noted in two patients with this syndrome.

Dermatitis Herpetiformis.—A man aged 78 suffering from this disorder did not obtain any relief on an arsenical mixture or 1/2 gr. (32 mg.) of phenobarbitone thrice daily. Antistin—

100 mg. four times a day—induced a mitigation of this symptom, but only during administration of the drug.

Lichen Obtusus Corneus.—A woman who suffered from a patch of lichen obtusus corneus in the left supraclavicular fossa for two years had been treated by occlusion of the area, infiltration with "novocain" and "proctocaine," Grenz rays, and x rays, as well as the usual antipruritic local applications, but without any lasting success. Antistin, 200 mg. by mouth, was prescribed for the attacks of irritation. A certain amount of relief followed. Finally the area was infiltrated direct with 100 mg. of antistin, no previous local analgesic being given, as antistin itself has a local analgesic action. Some improvement followed, and the manoeuvre was repeated in a month's time. A month later the lesion had disappeared completely, and no recurrence has been noted after four months' observation.

Lichen Planus.—Of four patients, two were almost completely relieved of the irritation during ingestion of the tablets, but two derived no benefit. One of these was a man aged 66, who complained of transient dizziness while taking 100 mg. four times a day by mouth. The actual course of the disease, and the appearance of the eruption, seemed to be unaffected.

Mycosis Fungoides.—A woman who had suffered from a generalized eczematous condition with marked pruritus for five years, and who ultimately disclosed the true nature of her disorder by developing typical nodules, confirmed histologically, obtained partial relief from her pruritus on this medication without any change in the lesions.

Pemphigus Vulgaris.—Owing to the unsatisfactory state of our knowledge in the treatment of this condition antistin was tried. Though it was administered to the limits of tolerance to two patients no improvement occurred. The effect of benadryl on one of these patients proved equally disappointing.

Senile Pruritus.—Two men, both aged 80, obtained relief, whilst under observation for four and three months respectively, on 100 mg. of antistin four times a day by mouth. A woman aged 72 found no reduction in the irritation on a similar dosage. Another man, aged 80, who obtained no benefit from antistin 100 mg. four times daily, suffered a transitory paresis of the left leg and collapsed while taking this dosage.

Pruritus Vulvae et Ani.—It was hoped that antistin would afford some relief in this condition. Among 14 patients suffering from pruritus vulvae or pruritus ani, or both, of idiopathic aetiology, none showed any consistent improvement. Neither did any benefit accompany or follow the use of benadryl in equivalent dosage.

Psoriasis.—A man aged 38 experienced considerable irritation during an exacerbation of his flexural psoriasis. Antistin afforded no relief.

Chronic Urticaria.—Sixteen patients with this disorder were treated over long periods. In 13, urticarial manifestations almost completely disappeared. In the majority this relief was noted 24 to 48 hours after starting treatment. Two more patients suffered mild undisturbing recurrences, and one other on his own assessment showed a 50% improvement. One derived no benefit. Four of these patients have been free from a recurrence for three to four months following two months' antistin therapy. Four of the persons forming this group also suffered from recurrent attacks of angioneurotic oedema. In one these gradually subsided and disappeared entirely after three months' treatment with antistin; one obtained complete relief when taking the tablets; whilst the other two still had recurrences, but these were milder and less frequent. Nine of these patients had been previously treated with benadryl. Five had developed drowsiness on their respective dosage and preferred to discontinue this treatment and retain their urticaria. Three patients who did not respond had only been given a maximal dose of 100 mg. thrice daily. One patient was equally well controlled on benadryl and "anthisan."

Urticaria Papulosa.—Six children suffering from this condition did not experience any mitigation of their itch on dose up to 100 mg. four times a day. Two children showed a reduction in the tendency to scratch. One child, aged 3, developed transient convulsions on 100 mg. three times a day. Cessation of therapy was accompanied by complete resolution of this disturbing symptom.

Surveillance and Investigations

Twenty-three patients had serial blood counts performed during two to three months' therapy. No significant variations were noted. Seventeen patients had serial blood-pressure estimations performed in the out-patient department over a similar period; six of these were over 70 years old, with arteriosclerosis and mild systolic and diastolic hypertension. Antistin therapy did not appear to cause any permanent significant alteration in the readings. Repeated urinalysis in 30 patients without albuminuria or glycosuria initially did not reveal the development of either during the course of treatment.

Discussion

Antistin is one of the three antihistamine substances available in Great Britain at the moment, the other two being benadryl and anthisan. The indications for the use of the first two in dermatology are, in my experience, identical, and there is little to choose between them in efficacy. One feature concerning the effects of benadryl therapy has repeatedly been observed—notably its high percentage of toxic manifestations which, though mainly mild, are sufficient to limit its sphere of usefulness. Among 120 patients Stroh (1946) found that 14.2% suffered from undesirable side-effects. Slater and Francis (1946) recount an incident in which the driver of an electric truck lost control over his machine while taking benadryl. Nervousness, incoordination, and epileptiform convulsions occurred in a child aged 3½ years who was being treated for hay-fever (Weil, 1947). Of McElin and Horton's (1945) patients 60% complained of sleepiness, 16% of dizziness, and 14% of nervousness. Koelsche, Prickman, and Carryer (1945) state that 25 among 83 patients complained of drowsiness. O'Leary and Farber (1945, 1946) noted that 33% of their patients suffered from toxic reactions. Friedlander (1946) found a similar incidence of side-effects. Again, among 696 patients treated with benadryl, 366 instances of drowsiness occurred (Ann Allergy, 1946).

Lack of its soporific and depressing effect I am reluctant to order benadryl for the motor driver, the skilled mechanic and operator, or others daily performing potentially dangerous tasks requiring a high degree of mental alertness and co-ordination. In my experience antistin has given equally good therapeutic results with a much lower incidence of untoward reactions.

There is, however, only a limited field of usefulness for this type of drug in dermatology; they effect a symptomatic alleviation, but not a cure. Those marketed to date may all cause immediate unpleasant side-reactions, and their remote toxicity has yet to be fully assessed. In some instances the amount of relief afforded justifies their use; in other disorders the same, or greater, relief can be obtained by well-tried, innocuous, and cheaper methods. In my experience, indications for the use of antistin are as follows.

1 *Urticaria and Angioneurotic Oedema*.—It affords marked symptomatic relief in the treatment of this condition while specific or non-specific curative measures are being used. It is often useful in reducing the polysusceptibility of certain cases when testing by scratch or intradermal methods.

2 *Eczematous Conditions with Oedema*.—It offers a useful addition to the dermatologist's armarium for expediting recovery.

3 *Itching in Other Skin Conditions*.—Occasionally it may prove helpful for mitigation of itching when the usual methods are ineffective.

Undesirable Reactions

"ANTHISAN" IN TREATMENT OF ASTHMA AND HAY-FEVER

BY

NEVILLE SOUTHWELL, M.A., M.D., M.R.C.P.

(From the Asthma Clinic, Guy's Hospital)

The unpredictable fluctuations which are a feature of the clinical course of asthma, together with the dauntless optimism with which asthmatics invariably welcome any new remedies, have always made clinical evaluation of these a matter of great difficulty. The very large number of initially encouraging reports of numerous different remedies in the past, now often totally abandoned, point reproachfully to the ease with which both doctor and patient are frequently mistaken in their estimate of the benefit conferred by the new preparation. It should be the duty of those who are interested in the treatment of asthma to assess as accurately as possible each new remedy, not only to protect practitioners and prevent disappointment to the long-suffering asthmatics themselves, but also to allow subsequent investigations of further new substances to proceed unhampered by erroneous and confusing estimates of the benefits of their immediate predecessors.

Reports from France and America on the clinical use of the new antihistamine substances (antergan, neonantergan, "benadryl," pyribenzamine) agree that good or even excellent results are obtained in the treatment of rhinitis, both seasonal and perennial, that markedly beneficial results follow the use of the drugs in various forms of urticaria and in some other dermatoses, that pruritus ani and vulvae and the pruritus of atopic dermatitis are often relieved and drug rashes benefited. Results in the treatment of asthma, however, are less certain.

Nevertheless enough has been published to encourage the belief that antihistamines do confer benefit in many cases of asthma, as Table I shows. From perusal of the American and French literature on antihistamines it is abundantly clear, however, that enough care has not always been taken to eliminate from the clinical trials those factors which contribute to erroneous clinical impressions. It is likely that herein lies the explanation of the otherwise irreconcilable variation in the apparent efficacy of these remedies in the hands of different workers.

TABLE I.—A Selection of Results with Benadryl in the Hands of Different American Workers

Author	Asthma (Seasonal)		Asthma (Perennial)	
	No. of Cases	No. Improved	No. of Cases	No. Improved
Levin (1946)	—	—	87	57
Waldrott (1946)	30	14	48	24
Koelche, Prickman, and Carryer (1945)	19	14	12	4
Blumenthal and Rosenberg (1946)	—	—	12	4
McElin and Horton (1945)	—	—	3	1
Eyer mann (1946)	—	—	4	3
Feinberg and Friedlaender (1946)	—	—	16	0

In most of the published reports on the antihistamines, especially in the treatment of asthma, clinical data are conspicuous by their absence. When authors write of their patients "deriving benefit," this statement is seldom amplified in any way, nor are the criteria of improvement indicated. In many cases the duration of the trial is not stated, nor, apparently, is the use of a control preparation thought to be necessary. These faults appear more plainly evident in those series in which the authors claim a high degree of improvement with antihistamines. To take a single instance, Levin (1946) reports the results of benadryl in the treatment of no fewer than 87 asthmatics, of whom

as many as 67% of the children and 65% of the adults "obtained relief." Apart from stating that benefit was less in those patients who had a cold, the author gives no information at all about the patients; nor is this example an isolated instance.

The Present Investigation

In this investigation an attempt has been made to assess as accurately as possible the effect of one of the antihistamine preparations in asthma and hay-fever. In order to eliminate those factors which tend to create erroneous impressions, the patients have been very carefully selected and critically observed both while taking the trial preparation itself and while taking an inert dummy preparation of identical appearance. So that the criteria of success or failure with the trial preparation should not consist entirely of verbal descriptions of patients' subjective sensations, a system of numerical grading of the severity of the symptoms has been adopted, with the object of obtaining a graphic expression of the effect of the trial preparation itself as opposed to the effect of the control.

The compound used in this trial has been one of the newest and most active of the antihistamine substances—namely, pyranisamine maleate ("anthisan"), which is chemically N-dimethylaminocetyl - N - P-methoxybenzyl - α -amidopyridine acid maleate, otherwise called neoantergan maleate. It is a colourless crystalline solid, soluble in water. The preparation has been kindly supplied by Messrs May and Baker put up in 0.1-g. tablets, coloured green, together with 0.1-g. tablets of identical appearance but composed of quite inert substances—namely, sucrose 50 g., lactose 350 g., starch 100 g.

Each patient has, unknown to him, received a quantity of the inert preparation alternating with the real substance. The initial dosage of both the inert and the real has been one tablet (0.1 g.) thrice daily. This has been increased to three tablets thrice daily after three days on the initial smaller dose. Patients suffering from nocturnal asthmatic attacks have also received 0.3 g. immediately before retiring at night.

The patients have been chosen from among those attending the Asthma Research Clinic at Guy's Hospital during 1946 and 1947. All have been under my direct observation.

Asthma Cases

The asthmatic patients comprised a mixed group of cases of different ages, sex, and duration, of various degrees of severity, with only one feature in common—namely, that all were examples of allergic as opposed to bronchitic asthma, with minimal infection and lung damage. However, although cases of primary bronchitic asthma were excluded from the trial, in the cases of very long standing there was bound to be emphysema and some degree of associated bronchial infection.

Twenty-five patients (12 male, 13 female) were included in the trial (Table II). Their ages ranged from 9 to 48 years. Most had perennial asthma, but some had seasonal exacerbations during June and July, over which period part of the trial was carried out. Of these patients 20 were well known at the clinic, and were particularly suitable for study, as either their asthma periodicity was regular or their symptoms were continually present. The remaining five were new patients with comparatively short histories, included in order to observe the effect of the preparation upon cases of recent onset. Cases 19 and 24 were excluded from the trial owing to the unexpected, startling, and sustained improvement that was produced by the inert control tablets.

The 20 patients had had a great deal of treatment both at Guy's and elsewhere. During the period of the trial it was not found practicable to withhold all other forms of treatment, and therefore, with the exception of the five new cases (Nos. 13, 21, 25, 26, 27), all the patients were instructed to continue with any palliative treatment to which they were

accustomed. The five new patients received the test substances only, and no other form of treatment. If they had been taking occasional ephedrine tablets these were withheld.

* Excluded from the trial. † Patients new to the clinic.

Hay-fever Cases

The hay-fever patients numbered 15 (Table III). All were skin-tested by the scratch technique and all were found to be sensitive to grass pollens. Cases 3, 9, and 14 were also sensitive to tree pollens. Four patients had asthma as well as hay-fever, but were not included in the asthma series as the unstable periodicity of their attacks made grading impossible. All the 15 cases had definite seasonal periodicity. Cases of perennial rhinitis were not included.

TABLE III.—*Hay-fever Cases*

Scheme of Trial and Methods of Assessment

Asthma

Grading.—All the patients in the asthma group were graded according to the severity of their symptoms in the past (Table IV). The system adopted was similar to that recommended by the Asthma Research Council (Committee on Assessment of Results in Asthma). In the present series,

TABLE IV.—*Grading of Asthmatic Patients*

Patient Series	Asthma Research Council	Symptoms
Grade 6	Grade I	Continual asthma. Patients who are unable to work at all or go to school.
Grade 5	Grade II	Continual asthma. Patients who are able to work or go to school 75% of the time.
Grade 4	—	Continual asthma. Patients able to work or go to school, but weary on at least one occasion during each 24 hours.
Grade 3	Grade III	Patients whose attacks occur at least once a week.
Grade 2	Grade IV	Patients whose attacks occur at least once a month.
Grade 1	—	Patients whose attacks occur less than once a month.

however, an additional grade has been included, and it has also been found convenient to reverse the grading numbers, so that Grade 1 represents the mildest type of case instead of the most severe.

Method.—The period of the trial for asthmatic patients extended over eight weeks, about half of which was spent on the active preparation, and the remainder, unknown to the patient, on the inert dummy tablets. For the first two weeks the dummies were used, after which the active preparation was substituted. After some weeks on the active preparation, patients returned to the dummies for a week or two before continuing with the active preparation. If a patient appeared to be showing a sustained improvement on the active preparation he was usually changed to the inert dummies.

At the start of the trial the patient was graded according to his past asthmatic history. At the end of each successive week of the trial he was regraded according to the severity of his symptoms during the preceding week. At the end of the eight-weeks period the average weekly grading number while taking the active preparation was available for comparison with the average weekly grading figure while taking the dummies. When the whole series of asthmatic patients had been investigated their average individual weekly grading numbers on the active preparation were added together for comparison with the sum total of the same figures whilst on the dummies (Table V).

TABLE V.—*Summary of Results in Asthma Cases*

* Not included in trial. U = Untreated. D = Dummy. R = Real.

It is not intended that any statistical significance should be attached to these figures. The grading numbers serve as convenient numerical symbols representative of the degree of severity of the asthma of each patient week by week. The figures, however, do bear a definite fixed relation to the severity of the symptoms, so that the sum total of the average weekly grading numbers for the whole group on the real, as opposed to the inert, preparation may be taken as a reflection of the summation of the severity of the asthma of all the 25 patients while taking neoantergan, compared with the severity of their symptoms while they were not.

Hay-fever

Grading.—The symptoms of hay-fever patients have been divided into four grades according to the severity—i.e., Grade 4, severe symptoms; Grade 3, moderate symptoms; Grade 2, slight symptoms; Grade 1, no symptoms.

Method.—A scheme similar to that used for the asthma patients has been devised for the hay-fever patients. Owing to the comparatively short duration of the symptoms in some

MEDICAL JOURNAL 879

cases the period of time on the dummy tablets has been curtailed to a week in most instances, while that on the active preparation has ranged from four to seven weeks. The results are shown in Table VI.

TABLE VI.—Summary of Results in Hay-fever Cases

Case No.	Weekly Grade Nos.	Average Weekly Grade Nos.		
		Untreated (u)	Dummy (d)	Real (r)

Average for series		3.8	3.73	1.5

Discussion

Before this investigation began a few cases of asthma and hay-fever had been treated with neoantergan, with apparently extremely disappointing results in the former and very encouraging results in the latter condition. The tentative impression of the powers of this drug thus created has been confirmed in striking manner by the more detailed observations on the series of cases summarized above.

In the asthmatic group the average of the weekly grading figures for the 25 patients observed over 105 weeks while taking neoantergan was 3.5. The equivalent figure for the same 25 patients observed for 89 weeks on the control tablets was 3.6, and before treatment was started the figure was 4. In other words, there appeared to be no appreciable difference in the severity of the symptoms while taking the drug, as opposed to the control tablets.

In contrast to the asthmatics, the severity of the symptoms of the 15 hay-fever patients while taking the preparation over a period of 69 weeks was indicated by the figure 1.5, whereas the severity of the symptoms of these patients observed over 21 weeks on the controls was indicated by the figure 3.7—a very striking contrast indeed.

These graphic expressions of results strongly reinforce the clinical impression of the benefit of the drug in this series—namely, that in asthma neoantergan appears to be of little or no value, whereas in hay-fever the symptoms have been partially or completely controlled in all the patients who were taking the preparation, including a number with severe symptoms.

The necessity for using a control preparation in an investigation of this kind is illustrated by asthma cases Nos. 19 and 24. Both these patients showed a great improvement in their asthma as soon as they began to take the dummy tablets, and not only was the improvement sustained throughout the period of the trial but both patients became worse when the dummy tablets were withheld. Case 24 was of particular interest, as this patient had previously been a severe asthmatic in Grade 4—a case of very many years' standing—and was also suffering from atopic dermatitis, which, however, remained unaltered in spite of the improvement in the asthma.

Even before this trial it was considered improbable that neoantergan would prove capable of influencing materially the severe asthmatics of Grades 5 and 6. It was to be hoped, however, that some of the patients with milder degrees of asthma might show some improvement—for example, those with only a moderate degree of daily or

nocturnal wheeziness or those who suffered from one or two mild attacks of short duration weekly. The published reports of other workers led me to expect some improvement in patients of this kind, but none was forthcoming which could with justification be ascribed to neoantergan: in fact, improvement in Grades 3 and 4 appeared just as likely to occur with the control as with the real preparation, and in any event was usually fluctuant and variable. For example, asthma patient No. 2, a severe case, had two good weeks as soon as she went on to the real preparation: but this improvement persisted even when the control was substituted, and when she finally did relapse the previous degree of improvement could not again be achieved with the active preparation.

It did not seem that a short duration of the patient's history favourably influenced the results with neoantergan. Asthma cases Nos. 13, 21, 23, 25, and 26 had all had asthma for less than a year, but none showed any improvement—in fact, Cases 13 and 21 actually appeared to be worse during treatment. Neither did the youth of this particular group of patients impart any salutary effect.

In spite of its soporific effect neoantergan conferred no apparent benefit upon patients whose asthma showed a nocturnal periodicity. For example, asthma case No. 7, a young clerk, had an attack every night with clockwork regularity, usually at about 3 to 4 a.m. This had persisted even during treatment as an in-patient, and sleeping by day instead of by night made no difference, the asthma again occurring some five hours after retiring to rest. This man received a large dose of neoantergan as a preventive immediately before getting into bed, but the attacks occurred just the same. Nor did the drug appear to exert any appreciable effect in relieving the established attack, which, however, invariably responded to adrenaline. It was of particular interest to note that after the trial was over Cases 16, 18, 20, 21, and 26 improved at once on adrenaline, which they had not previously taken, except occasionally. The improvement was sufficient to move Cases 21 and 26 down a grade as soon as they had mastered the technique of self-injection of adrenaline.

In addition to the object-lesson of Cases 19 and 24, both of whom did so well on the inert control tablets, another point of interest emerges from the grading results—namely, that the patients' grading figures (3.6) during the trial while taking the dummies were considerably lower than the figures (4) for the same cases before the trial, in spite of careful assessment of the grades based on previous observation of the individual patients over periods of time ranging from several months to several years. It is easy to see how, if a control preparation had not been used, such a change in symptoms could be mistaken for an improvement due to the test drug.

There can be no doubt at all of the value of neoantergan in the symptomatic treatment of hay-fever. In addition to the striking changes in the grading figures while taking the preparation (1.5) compared with the figures on the dummies (3.7), the patients themselves were unanimous in their praise of the preparation, although disappointed during periods on the dummy tablets. Some of these patients had had pollen-desensitization courses in the past, several of them more than once. They declared that the most success conferred as much protection as any but the most successful desensitization course. Two patients, not included in the trial, were treated with a high degree of success with neoantergan, which was started half-way through the season when their pre-seasonal desensitization course was found to be not wholly effective.

Side-effects.—Of the 42 patients reported in this trial side-effects were noted in 23—10 had slight nausea, 6 nausea and drowsiness, 4 drowsiness, 1 impotence, and 2 giddiness.

Conclusions

Neoantergan conferred no apparent benefit upon 25 specially selected and carefully observed asthmatic patients.

Neoantergan was markedly successful in reducing the severity of the symptoms of 15 cases of hay-fever.

When working with asthmatic patients an erroneous impression of the efficacy of a new preparation is likely to be formed unless a very careful scheme of trial is planned, preferably using a control preparation.

It is with pleasure that I acknowledge the help received from Dr. W. N. Mann during this investigation, and I am grateful to Dr. W. R. Thrower, of Messrs. May and Baker, for kindly supplying the anthisan. This work is an abstract from part of a Cambridge M.D. thesis, and for permission to publish it I am indebted to Sir Lionel Whitby, Regius Professor of Physic, Cambridge University.

CHIASMA LESION DUE TO FALL IN EPILEPTIC FIT

BY

R. KLEIN, M.D. Prague

AND

P. P. O'MALLIE, M.B., M.R.C.P.I., D.P.M.

(From the Bristol Mental Hospital)

Damage to the optic nerve due to a fall in an epileptic fit is surprisingly rare, although optic-nerve lesions may follow slight head injuries. Chiasmal damage occurring after epileptic seizures has not been previously recorded in the literature. The following case, which ended in optic atrophy and blindness in one eye, is of special interest because of its unusual course and visual-field changes.

Case Report

The patient, a single man aged 32, suffered from epilepsy, probably of traumatic origin. Generalized fits followed a severe head injury sustained six years before. These occurred at intervals of one to two months, with sudden falls and no aura. At the end of November, 1944, he fell on his forehead during a fit. There was a swelling over the right eye due to extravasation of blood. He was confused for the rest of the day, as usual after his seizures. Next day, when mentally clear, he complained of blindness in his right eye. Examination revealed a complete loss of vision in this eye, and a marked temporal-field defect of the left eye with normal visual acuity. This was evident in subsequent examinations. Simple and stereoscopic x-ray examination of the skull immediately afterwards did not show any fracture.

About a fortnight after the accident there was a distinct difference in the two disks, the right being paler. After a month there was an obvious atrophy of the right disk, with pallor, narrowing of the large retinal arteries, and reduction of the small vessels. This condition was still unchanged when a complete examination of fundus, visual field, and acuity was carried out in May, 1945, six months after the accident. Since further developments were not anticipated no regular examinations were made. On July 17, 1945, however, the patient reported that a few days previously he had begun to see again with the right eye and that vision had gradually improved. A further examination showed a central scotoma in his right

eye with full peripheral visual fields. The visual acuity for finger-counting was 3 ft. (0.91 metre). An examination two days later showed that the central scotoma had disappeared and that the acuity had risen to 6/9. The visual field in the left eye still showed some temporal defect, but to a less degree than in the first period after the accident.

On Aug. 2 he reported that the sight of the right eye had again become worse, and attributed this to an injury inflicted by a patient, who he alleged threw lumps of soil into his face. He also stated that a few days previously he had had to bend his head while helping with weeding in the garden. The visual field two days later showed a central scotoma and a concentric constriction of the peripheral field; the visual acuity had fallen to 1/60. Subsequent examinations showed that the scotoma gradually increased in size, the peripheral field became more and more restricted, leaving eventually a pericentral annular island of vision, and within a week the patient was again blind in the right eye. The visual field of the left eye showed no definite temporal defect during this phase. The direct pupillary reaction to light in the right eye was from the beginning of the observation sluggish and poor, decreasing in the first week after the accident until it became fairly stable after the atrophy of the optic nerve had been established. No definite change was noted during the short spell of recovery. Up to January, 1948, no further change has occurred; the right eye remains blind, with atrophy of the disk; the left eye shows full visual field and normal acuity. The direct light reaction, though very poor, is still obtainable.

Discussion

Complete blindness and optic atrophy of the right eye after a fall in an epileptic fit, and a temporal-field defect of the left eye, pointed to a lesion in the chiasmal region affecting the fibres of the right optic nerve and the nasal retinal fibres from the left eye. This type of injury has been repeatedly discussed in the literature. The skull fracture which often accompanied such lesions suggested a direct traumatic damage to the nerve, and specimens have been shown in which the nerve in this section had actually been torn. Early writers were mainly concerned with the possible types of skull injury which might produce this nerve damage. Various mechanisms have been suggested (Liebrecht, 1912; Coppez, 1929; Rand, 1937), but more recent experience has made it clear that bone injury and anatomical nerve lesions are not the only cause of the traumatic chiasma syndrome, and that vessel damage alone may have the same effect and produce the initial symptoms (Traquair, 1933, 1942; Dandy, 1932; Rodger, 1943; Hughes, 1943). Rodger differentiates bleeding into the sheaths and subvagal and intraneural haemorrhages.

There can be little doubt that in our patient there was a vascular lesion; the remission and subsequent relapse cannot be explained in any other way. The fact that central vision was the last to return when the recovery took place, and that a central scotoma was the first symptom when the relapse occurred, seems to indicate an intraneural damage. The onset immediately after the injury is in favour of traumatic rupture of the vessel wall, with consequent intraneural haemorrhage (Rodger, 1943). This would also account for the relapse. After a slight injury the vessel, which had been closed, started to leak again causing a gradually increasing extravasation—a mechanism well recognized in meningeal and brain-vessel damage when a minor incident may cause renewed extravasation long after the initial trauma.

With regard to the progress of our case the changes during the first few weeks after injury were as anticipated. It is the general experience that a visual-field defect and loss of visual acuity occur immediately after the injury, while atrophy of the optic nerve usually appears within four weeks. In seven cases of optic-nerve lesions Rodger (1943) noted an average interval of 17 days, the shortest

interval being four days. In our case blindness set in immediately after the accident, and atrophy was distinct after a fortnight.

Concerning the prognosis of these cases there has been general agreement (Traquair) that if no signs of improvement in visual acuity occur during the first four weeks no further change can be expected. But in our patient there was a rapid and almost complete recovery as late as five months after the injury. This is difficult to explain; it is contrary to all experience that recovery should have occurred after so long a time. One might think of a hysterical fixation of an original organic blindness, but nothing was observed in the general behaviour of the patient to support this, and there were no psychogenic elements. There were, on the other hand, optic atrophy and a transitory scotoma—findings which do not permit a functional explanation.

It is likely that the primary site of the lesion was in the anterior chiasmal angle, affecting mainly the right optic nerve but also damaging the crossed fibres of the left. It is interesting to note that the temporal-field defect of the left eye gradually diminished and had entirely disappeared after the relapse. We will therefore have to assume that on this occasion the chiasma had been spared, the lesion being restricted to the right optic nerve.

Summary

A case is reported in which blindness and optic atrophy in the right eye, with a temporal-field defect in the left eye, followed a fall in an epileptic fit. X-ray examinations of the skull were negative. There was no fracture.

Not less than five months after the injury normal visual acuity with full visual fields in the left eye were re-established; during this period of recovery central vision was the last to return to normal. The temporal-field defect in the left eye was the same time greatly reduced.

Shortly afterwards, following a trivial blow on the face, his sight and visual-field condition deteriorated, a gradually extending central scotoma appeared, and visual acuity fell rapidly until the right eye became blind again. There was no temporal-field defect in the left eye at this time. Atrophy of the right optic disk remained unchanged during the whole period. There was no further change one year later.

Dr. Esmond R. Long, director of medical research and therapy, National Tuberculosis Association, has been appointed editor-in-chief of the *American Review of Tuberculosis*, official journal of the N.T.A.'s medical section, the American Trudeau Society, to succeed the late Dr. Max Pinner. A new position of managing editor has been created, and Dr. Walsh McDermott, associate professor of medicine, Cornell University Medical School, New York, has been appointed to the post. Dr. Long, who is also director of the Phipps Institute, Philadelphia, has been director of the N.T.A.'s medical research since January, 1947. He is a past president of the N.T.A. and is a consultant on tuberculosis to the United States Army, the Veterans Administration, and the U.S. Public Health Service. A graduate of the College of Physicians and Surgeons, Columbia University, Dr. McDermott is associate attending physician of New York Hospital and was associate editor of the seventh and eighth editions of the *Cecil-Loeb Textbook of Medicine*. He is a member of the American Trudeau Society's Committee on Medical Research and Therapy and of the Antituberculous Study Section and the Tuberculosis Study Section, National Institute of Health, U.S. Public Health Service.

JUVENILE GENERAL PARALYSIS

A CASE WITH A SPONTANEOUS BUT SHORT-LIVED REMISSION

BY

W. LIDDELL MILLIGAN, M.D., B.Sc.

Deputy Physician-Superintendent, St. James Hospital,
 Portsmouth; Deputy Director, Portsmouth Mental
 Health Service

Although a considerable number of cases of juvenile general paralysis have been reported in the literature the disease is relatively rare and its incidence in cases of congenital syphilis is stated by Stewart (1933) to be about 1%. Schmidt-Kraepelin (1920) gives the figure as 1.7%, but White and Veeder (1922) and Smith (1933) are in agreement that the incidence is less than 1%. Most authorities agree that the sex distribution is approximately equal, although there is a slight tendency towards a preponderance of males; thus out of 145 cases reported by Mott (1899), Watson (1903), Schlicht (1915), Schmidt-Kraepelin (1920), Klauder and Solomon (1933), and Menninger (1930), 83 were males and 72 females. According to Menninger (1936) there are two types of onset, the first being insidious, when the child is apparently subnormal from birth, and the second in which an acute breakdown occurs after several years of seemingly normal development. Menninger in an analysis of 542 cases gives the age of onset as 3 to 5 years in 9.4%, 6 to 10 years in 24%, 11 to 15 years in 36.2%, 16 to 20 years in 26.8%, and 21 to 25 years in 3.6%. In the majority of cases, therefore, the illness begins between the ages of 10 and 15. Menninger states that in a series of 653 cases psychic trauma was regarded as the precipitating factor in 2.7%, and that convulsions occurred in 17% before the diagnosis was established.

Case Report

A boy, aged 11 years 3 months was admitted to this hospital in November, 1946, as he was not responding to outpatient treatment at a child-guidance clinic in another area.

Family History.—The father, a Naval petty officer aged 38, was stated to be fit and well. He has had little to do with the boy's upbringing owing to his service overseas. When interviewed in December, 1946, he admitted that he had had primary syphilis in 1929 but had received a full course of treatment over two years. His Wassermann reaction was: blood +, C.S.F. negative. He was having treatment at a V.D. clinic. The mother, aged 36, is fit and well. She is a kindly woman, but ineffective in handling the family and lacking in understanding. Her Wassermann reaction was: blood +, C.S.F. negative. She has had no treatment. **Siblings:** There are three sisters, aged 16, 7, and 4. All are bright and alert, with negative serology.

Personal History

The boy weighed 8 lb. 12 oz. (3.98 kg.) at birth, walked at 12 months, and began talking at 15 months. Clean habits were established early, and he appears to have been a perfectly normal child until a few days before his fifth birthday, when his home was destroyed by enemy action. He was uninjured, but was said to have screamed persistently for several hours after the incident. He was apparently terrified during the next three days, and there were many outbursts of screaming during this time. On the fourth day he had an epileptiform attack during which he exhibited loss of consciousness and left-sided rigidity followed by generalized clonic movements. In the succeeding nine months he had frank epileptic major attacks with incontinence and tongue-biting at the rate of about one a week. These persisted despite anticonvulsant drugs prescribed by his doctor. During this time he progressively became more dull and was excessively timid and anxious. There was, in fact, a complete personality change, and whereas he had formerly been a bright, cheerful, alert, self-possessed child, he now became very quiet and reserved, and was made fun

of by other children. Six months after the original epileptic manifestation he was seen by a children's psychiatrist, who stated that he was suffering from an anxiety state but that no special treatment was required. Shortly before this it had been noticed that he was becoming very clumsy and had very great difficulty in picking up objects. It was also noted that he had to be assisted in dressing, as he was unable to do up his buttons or tie his shoe-laces. His speech, which had previously been quite clear, became slurred, and his parents and teachers had difficulty in understanding what he was trying to say.

In July, 1942, the family moved to Scotland, and shortly after this a remarkable change was noted in the child. In the course of a few months he completely lost all signs of muscular incoordination, his speech became clear, he regained confidence, and he began to stand up for himself with other boys. He rapidly made progress in education, and during the next two years became recognized as one of the best scholars in his year. Evidence of this exists in the fact that he was awarded several books as prizes in arithmetic, writing, spelling, and drawing. In September, 1944, the family moved to another area and very shortly John's condition began to deteriorate once more. His standard at school fell rapidly, but his mother attributed this to the change of school. By February, 1945, however, it became obvious to his parents that his symptoms were exactly similar to those noted at the age of 5. A school report in May, 1945, noted him as "dull and backward" but "very nervous." He was accordingly referred to a child-guidance clinic and was treated as a "maladjusted child." His I.Q. was reported as 100. It is of interest to note that his mother had observed that his drawings were becoming completely indecipherable, being entirely obscured by a wealth of unnecessary detail. As three months' treatment did not make any impression on the child, but on the contrary had failed to prevent deterioration, he was sent to this hospital for in-patient treatment.

On examination he was a plump, awkward-looking child who was very restless and apprehensive. It was noted that the incisors were of the Hutchinsonian type. Gross motor incoordination was present, and this rendered him ludicrously clumsy. Slurring of articulation was a prominent feature, and although the pupillary responses were fairly normal there was irregularity of the margins. Tongue tremor was present and all reflexes were exaggerated; plantar responses were flexor. He was dull, slow in comprehension, and his I.Q. was found to be 69. The diagnosis of juvenile paresis was confirmed by a triple positive Wassermann reaction in both blood and cerebrospinal fluid and a paretic gold curve in the Lange test.

Since admission his condition has continued to deteriorate despite treatment, and he now falls about, has numerous epileptiform attacks, is incontinent, and requires constant nursing care and supervision.

Discussion

The above history has been carefully checked by reference to practitioners who previously treated the child, to teachers, and to others. It will be noted that the onset was just before the age of 5. So far as can be ascertained there are only 14 cases recorded in the literature in which the age at onset was the fifth year. Spontaneous remission is indeed very rare, and Stewart (1933) states that "the disease is never interrupted by a remission." On the other hand, Alzheimer (1895), Thompson and Dawson (1895), and others have recorded instances of spontaneous remissions, but the total number of cases does not exceed 20. Most authorities agree that the prognosis in such cases is very poor, and Lurie *et al.* (1943) report on 8 cases of juvenile paresis seen at the Cincinnati Child Guidance Home. Despite early diagnosis and treatment all these children showed progressive mental and intellectual deterioration.

It is fact that this boy was examined by two child psychiatrists and treated by one for three months should make clear the need for a careful physical examination of all children at child-guidance clinics. In this connexion it is interesting to note that out of 125 in-patient children

reported by Barker and Milligan (1947) 13 were found to be suffering from organic disease of the nervous system and only three of these cases had been diagnosed as such before admission to hospital.

Summary

A case of juvenile general paralysis is described, with an onset at the age of 5 and an apparently complete spontaneous remission of two years' duration.

I wish to thank Dr. Thomas Beaton, Physician-Superintendent, St. James Hospital, Portsmouth, for permission to publish this case record.

Medical Memoranda

Gastric Herpes Zoster

The following report of a case of haematemesis due to gastric herpes zoster is worthy of record.

CASE HISTORY

A diabetic woman aged 66 was admitted in a precoma condition with a blood sugar of 450 mg. per 100 ml. She had been under regular observation in the diabetic clinic, and had no history of gastric symptoms. One year previously she had fallen and bruised her left lower ribs, and since that time she had noticed intermittent vague pain in the same region. A week before admission this had become constant and more severe, radiating round to the left abdomen. Four days later, feeling ill, she remained in bed, and at noon had a sharp haematemesis. At 3 p.m. she noticed a rash on the abdomen to the left of the umbilicus. On account of her malaise she discontinued both food and insulin; her diabetic precoma was the direct result.

On examination, apart from the signs of dehydration, she showed slight central epigastric tenderness. A typical eruption of herpes zoster was present on the left chest and abdomen, apparently involving thoracic segments 9 and 10. The rest of the examination was normal. Her diabetic condition was successfully treated, but unfortunately it was severe enough to preclude gastroscopy. A barium meal x-ray film eight days later was normal, and a fractional test meal showed complete achlorhydria. Haemoglobin was 90%, and rose subsequently with treatment. A radiograph of the spine and ribs was normal. The cerebrospinal fluid on admission contained 70 mg. of protein per 100 ml. and 23 lymphocytes per c.mm. Nine days later the protein was 50 mg. and there were 10 lymphocytes.

COMMENT

The sympathetic supply of the stomach by way of the coeliac plexus almost certainly includes branches from the ninth and tenth thoracic nerves. The appearance of the somatic eruption within three hours of the haematemesis is very suggestive of a true gastric herpes zoster as the origin of the latter. The relation of the previous injury to the herpes is of interest. Although there was no evidence of bony injury, it is possible that the repeated painful stimuli from an organized haematoma in muscle may have been sufficient to render the affected segments liable to attack by the virus. The cerebrospinal fluid changes are typical of those found in herpes zoster.

I wish to thank Prof. T. H. Oliver for permission to describe this case.

KEEPING FIT

Physical Fitness Appraisal and Guidance. By Thomas Kirk Cureton, Jr., M.A., M.P.E., Ph.D., assisted by Frederick W. Knoch, B.S., M.S., John Brown, B.S., and W. G. Moss, M.S., Ph.D. (Pp. 566; illustrated. 30s.) London: Henry Kimpton. 1947

What does physical fitness mean? This, the opening sentence of this remarkably comprehensive work, prompts the supplementary inquiry, Fit for what? In the past, attention has been particularly, indeed almost exclusively, directed to the circulation as the limiting factor in physical endurance. It is clear that specific tests must be instituted to assess capability for a particular purpose; for emotional, mental, and social fitness are also important in adaptation to life and living—problems which, the author indicates, will be investigated in future. As we must repeat *ad libitum*, perhaps *ad nauseam*, it is to the U.S.A. that we look for research in this subject. Interest and opportunities there permit grand-scale organization and operations with unlimited subjects for investigation, luxurious equipment, and staff to conduct the investigation. All of these are effected in the present work—a stupendous compilation of details, page after page of charts and graphs and columns recording the results of tests of physical fitness and physique ratings.

What are the conclusions? To a great extent only an elaboration of the obvious, a reminder of what is already known, repetition of the opinions expressed by workers in all parts of the world. We see, however, the beginning of an important study of "body types." "Just as we can purchase 10 dollar suits or 100 dollar suits so some of us inherit 10 dollar organs and others 100 dollar organs." How far can we estimate frailty and longevity on the basis of certain constitutional body types? We see in this work's subtitle the claim that "appraisal" permits of "guidance" to utilize natural advantages to the utmost, to accept the limitations imposed by natural deficiencies and so avoid disappointments in attempting to achieve the impossible.

The student of athletics will look for references to the super performer. In a chapter entitled "Analysis and Prediction of All-out Athletic Performance" the author speculates on the factors governing the quality of great endurance. He quotes (from *Cardiologia*, 1945, 9, 313) Gustav Nylin's investigation on the blood circulation of Gunder Hägg and Arne Andersson, the great Swedish middle-distance runners who broke several world records. It is interesting to learn that the most elaborate observations could only confirm the clinical examination which was made when these athletes visited Britain two years ago in the conclusion that no specific explanation was forthcoming of their remarkable performances. It is simply a matter of superior co-ordination of all the factors concerned in violent exercise.

The authors include a table of the "calorie value" of all forms of physical exertion from knitting to sprinting at full speed, which underlines once more the popular misconception that obesity can be treated by exercise. Doubtless exercise contributes to its reduction so long as dietetic restrictions are simultaneously imposed. The fat man will be dismayed to learn that in order to work off a pound of fat it is necessary to walk 66½ miles at the rate of 3½ miles an hour, which is a fairly strenuous pace for the average person of sedentary habits, or to run at full speed (10 yards per second) for 7½ miles, were this humanly possible.

ADOLPHE ABRAHAMSON.

PRACTICAL BIOCHEMISTRY

Laboratory Instructions in Biochemistry. By Israel S. Kleiner, Ph.D., and Louis B. Dotti, Ph.D. Second edition. (Pp. 245. 12s. 6d.) London: Henry Kimpton. 1946.

This manual of practical biochemistry is primarily intended for medical students. The selection of material and the standard of instruction are good, being based upon several years of practical experience in New York Medical College. The book compares favourably with manuals used by medical schools in

this country which for some inexplicable reason rarely seem to reach the publisher's office. The authors cover the basic requirements of clinical chemistry well, and as an innovation include accounts of such estimations as acid and alkaline phosphatase, cholesterol-ester ratio, and Bratton-Marshall's method for sulphonamides. There is a new section on analysis of cerebrospinal fluid, and a courageous attempt has been made to introduce the student to blood-gas analysis. With the development of the technique of heart catheterization such analysis will become of considerable clinical importance.

The book suffers from the disadvantage of all practical manuals in that, divorced as it is from its theoretical background, it lacks continuity with the course in organic chemistry which should precede it and the course of clinical chemistry which should follow. A practical account of a simple metabolic investigation is welcome; it is a feature which might with advantage have been extended to cover a few simple clinical tests. Students in Britain will find it difficult to carry out the instructions on experimental diets. The quality of the paper, which for the most part is printed on one side only, is first class. A novel plastic binding allows individual pages to be removed and gives the book an attractive appearance; nevertheless, it is unlikely that it will survive even normal use for more than a few years, and a more orthodox and permanent binding would have been preferable.

A PHYSICIAN'S PHILOSOPHY

The Philosophy of a Scientist. By R. G. Gordon, M.D., D.Sc., F.R.C.P.E.D. (Pp. 206. 16s.) London: Hutchinson's Scientific and Technical Publications 1948

The contributions of members of our profession to philosophy, in all senses of that word, have been illustrious. Speaking of Locke, Dugald Stewart wrote

"No science could have been chosen, more happily calculated than Medicine, to prepare such a mind for the prosecution of those speculations which have immortalized his name: the complicated and fugitive and often equivocal phenomena of disease, requiring in the observer a far greater proportion of discriminating sagacity than those of Physics, strictly so called; resembling, in this respect, much more nearly, the phenomena about which Metaphysics, Ethics and Politics are conversant."

Some readers of Dr. Gordon's thoughtful treatise may think that he quotes over-abundantly, and a reviewer certainly should eschew quotations, but the following passage illustrates happily what Dugald Stewart had in mind

"There are some people who think a little, that their sole philosophy is to do as their neighbours do and conform to the customs of the tribe, whether that tribe be a community of primitive savages or a social set in a provincial town. This may work well enough so long as things go on relatively smoothly and the tribe remains a coherent body, but if some upheaval occurs, whether in the personal life of the individual or in national politics, which flings them out of their envelope of protective custom, these people may become very lost and very distressed. They are apt to suffer from one variety of what is popularly called a nervous breakdown. This may cause them the more distress in as much as, previously, they have thoughtlessly adopted the attitude of insolent superiority, bred of ignorance and prejudice, with which their set have regarded those suffering from something which they do not understand. To find that they themselves are afflicted with such a complaint fills them with such shame that they insist that they must be suffering from some organic disease, which in their eyes is much more respectable and for which they would expect full sympathy, which they would never dream of extending to their miserable neurotic brethren."

Perhaps that admirable passage may attract colleagues to whom the word philosophy is as repellent as the word ideology to the reviewer. Dr. Gordon's philosophy, like that of Horace, is:

Aequè pauperibus prodest, locupletibus aequè,
Aequè neglectum pueris senibusque nocebit.

It appertains to what in the eighteenth century would have been classed as natural theology, but Dr. Gordon's knowledge of twentieth-century science is more exact than the knowledge eighteenth-century deists had of Newtonian mathematical

physics. Dr. Gordon sets out fully the difficulties which a consistent philosophy of the universe, or theology, must reconcile and insists that each man must face those difficulties for himself: he may end by reaching conclusions long ago pronounced, but they must be his conclusions. As the first Marquis of Halifax said, "Men who borrow their opinions can never repay their debts." It is not a sneer but a psychological truth that each man must make his own God: yet the result may not differ superficially from the God of a "revelation." It differs, however, fundamentally in as much as it is realized by the individual. Dr. Gordon's holistic conception of the soul and Aristotle's entelechy do not seem very different, but the two philosophers have travelled by different routes.

Dr. Gordon's philosophy is optimistic. He believes in ethical progress and reminds us that, on a cosmic time scale, civilization is young. Perhaps one needs more than an average degree of altruism to be comforted by his argument, but certainly an honest student will learn from Dr. Gordon's book some useful lessons in self-discipline.

MAJOR GREENWOOD.

GROWTH OF A VOLUNTARY HOSPITAL

The Story of a Scottish Voluntary Hospital. The Royal Northern Infirmary, Inverness. By T. C. Mackenzie, M.D., F.R.C.P. Ed. (Pp. 279. 8s. 6d.) Inverness: The "Northern Chronicle" Office.

The author of this interesting study of the inception and growth of a typical Scottish voluntary hospital presents a panorama in miniature of the changing social standards and advances in medical practice during the past 150 years against a background of the detailed administration and inevitable development of a living institution meeting an increasing need. Conceived in 1797 as a means of affording effectual aid to the sick poor in the Highlands of Scotland, and nurtured through the years by the generosity and devotion of succeeding generations of public-spirited individuals, the Inverness Infirmary has grown from small beginnings into the Royal Northern Infirmary, the acknowledged medical centre for the Northern Region of Scotland. The author has compiled the story from contemporary records and reports, and excerpts from the minutes of the Weekly Meetings of Committee give colour and human interest to the recurring pattern of increasing demands having to be met by increasing expansion and greater efforts to enlarge the funds. From the earliest days the interest of the managers and staff in the detailed administration of the hospital is clear—even concern about the vagaries of the Infirmary cow is recorded—as well as their interest in the welfare and progress of the patients.

To the student of medical and social history interesting glimpses are afforded of the values, human and monetary, accrued in the early part of last century. It is startling to realize that the provision for the "lunatic poor" consisted of cells 8 feet square and that in 1811 one of the staff reported to the Committee that a female lunatic who had been in the Asylum for nearly 12 months "was so far recovered, that she might be allowed to leave her cell with safety, but as she was quite destitute of cloaths being literally in a state of perfect nudity, the doctor suggested the propriety of furnishing her with some." Fifty years before Florence Nightingale the nurse ranked with the cook and chambermaid, with a wage of £4 yearly, and the matron's wage at £10 was less than the ward-maid's.

The book throughout illustrates clearly the gradual evolution of the voluntary hospital, which through the initiative and enterprise of private individuals has constantly been in advance of public authorities in meeting the needs of the community. As the author states in his preface, the knowledge of such a history is of special interest and importance at the present time, as the trend of events points to the assumption by the Government of departmental and possibly bureaucratic direction of the sphere of hospital work. Dr. Mackenzie's lucid and judicious account and a mature understanding of the subject are qualities which we hope that many readers who think that the history of medicine has been found much of interest in this book.

E. A. COPMACK.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

Males and Females. By R. Pilkington. (Pp. 92. 6s.) London: Delisle, 1948.

An introduction to the physiology of sex for adolescents.

Education and Health of the Partially Seeing Child. By W. Hathaway. 1st ed. Revised. (Pp. 216. 14s.) London: Geoffrey Cumberlege, 1947.

Intended for teachers, administrators, and nurses.

Congenital Malformations. By D. P. Murphy, M.D., F.A.C.S. 2nd ed. (Pp. 127. 30s.) London: J. B. Lippincott, 1947.

A practical introductory account of the causes of congenital malformations.

Diagnosis in Daily Practice. By B. V. White, M.D., and C. F. Geschickter, M.D. (Pp. 693. £4 10s.) London: J. B. Lippincott, 1947.

A textbook of diagnosis intended for the general practitioner and house-man.

Restoration Exercises for Women. By E. Rout. Preface by Sir Arthur Keith, F.R.S. 9th ed. (Pp. 84. 7s. 6d.) London: William Heinemann, 1948.

Physical exercises described and illustrated for women.

The Care of the Teeth. By G. H. Russell, M.B., Ch.B., L.D.S. (Pp. 48. 2s.) Altrincham: John Sheratt, 1948.

Instructions for the mother on the care of her own and her baby's teeth.

How to Become a Pharmacist. By W. A. Muteham, M.P.S. (Pp. 120. 5s.) London: The Actinic Press, 1948.

An outline for prospective entrants to pharmacy.

The Metabolic Brain Diseases and Their Treatment. By G. T. Stoekings, M.B., B.S., D.P.M. (Pp. 262. 16s.) London: Baillière, Tindall and Cox, 1947.

The author discusses the physiology and chemistry of physical therapies and compares these with psychotherapeutic methods.

A Manual of Pharmacology. By T. Sollmann, M.D. 7th ed. (Pp. 1,132. 57s. 6d.) Philadelphia and London: W. B. Saunders, 1948.

Intended as a comprehensive outline of modern knowledge of pharmacology.

Sport und Kreislauf. Edited by Dr. A. Wander. (Pp. 154. 12.80 Swiss francs.) Bern: Medizinischer Verlag Hans Huber, 1947.

Papers on the circulatory system in relation to athletics.

La Streptomycine. By Prof. C. Levaditi. (Pp. 218. 350 francs.) Paris: Presses Documentaires, 1947.

A monograph on the preparation of streptomycin and its clinical and experimental applications.

Das Psychoanalytische Volksbuch. Edited by Federn and Meng. 4th ed. (Pp. 736. 24.50 Swiss francs.) Bern: Hans Huber, 1939.

An exposition of psycho-analysis for the layman.

Erkennung und Unterscheidung akuter innerer und ansteckender Krankheiten. By Prof. A. Sylla. (Pp. 456. R.M.18.) Berlin: Urban and Schwarzenberg, 1948.

A textbook of acute diseases and communicable diseases.

Melk in het bijzonder als Zuigelingenvoedsel. By Dr. J. H. de Haas and Ir. O. Meulemans. 2nd ed. (Pp. 112. No price.) Batavia, N.E.I.: Tweede Druk, 1940.

A monograph on the composition of milk.

Histopatología d'una Nova Capa d'Epiteli Semiescamós pla que Cobreix les Mucoses Digestives. By F. D. i. Jorda. (Pp. 83. No price.) Barcelona: L'Institut d'Estudis Catalans, 1947.

An account of a "semi-squamous epithelial layer covering the gastric and intestinal mucosae" which the author claims he can demonstrate.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY MAY 8 1948

THE PLEBISCITE RESULT

The present plebiscite, the results of which are analysed on another page, shows that the concessions made by Mr. Bevan have persuaded many medical men to change their attitude to the Act and their decision whether or not to enter the Service on July 5. In the plebiscite of February there was a 9 to 1 majority in an 84% poll against the Act. In this plebiscite approximately 2 out of every 3 doctors in a 77% poll disapprove of the Act, notwithstanding the concessions Mr. Bevan has made. The figures show that some of those who disapprove of the Act are nevertheless prepared to enter the Service on July 5. In answer to Question B—the most important question of the three—12,799 medical men in England and Wales and Scotland are in favour of accepting service, and 13,891 are not in favour. The group which answered this question contains those directly affected by the Act—consultants and specialists, general practitioners, and whole-time voluntary hospital workers. There is an almost even division of opinion—48% willing to enter the Service and 52% unwilling. The number of general practitioners (principals and assistants) against accepting service is 9,588. Although there is an overall majority against accepting service, the majority does not include approximately 13,000 general practitioners. The majority the B.M.A. required if it was to continue to advise the profession not to enter the Service has, therefore, not been obtained.

This *Journal* went to press while the Council met on Wednesday to receive the results of the plebiscite and to consider what action should be taken. While it may be agreed that the Council is faced with a difficult problem, Mr. Bevan is faced with one which is equally, if not more, difficult. Opinion as expressed in Parliament and in the Press welcomed his statement in the House of Commons on April 7 as being a real attempt to break the deadlock—an attempt, moreover, made in such a manner that showed Mr. Bevan was making a genuine attempt to conciliate those whom he had previously offended. His gesture, we suggested in a leading article in the *Journal* of April 17, warranted an equally generous response. The B.M.A. Council recognized the concessions made by Mr. Bevan, and in a temperately worded phrase stated that these concessions did not offer sufficient safeguards for the essential freedoms of professional life. The medical profession as a whole, in continuing to disapprove of the Act, supports the Council's view. In the last plebiscite each of the eighteen groups of medical men answering Question A disapproved of the Act in substantial proportions. In this plebiscite all except three of these groups still disapprove of the Act, though not so strongly as last

time. Those approving include the salaried consultants or specialists, the whole-time teachers, and the whole-time research workers. But the majority of those employed whole-time in the Public Health Service still disapprove of the Act, and so by a very small majority do those working whole-time in Government service. A large majority of those holding permanent commissions in the Services are still in opposition. These facts cannot be ignored either by Mr. Bevan, or by the public, or by the medical profession.

In the last plebiscite 17,000 general practitioners were not prepared to enter the National Health Service. Those who still hold to this opinion now number 9,588. This figure falls far short of the 13,000 considered to be necessary in order to justify collective opposition to the Act, and the B.M.A. Council would therefore not appear to have a mandate to recommend such a course to the Representative Body. To organize collective opposition on such an insecure basis would be disastrous whatever the merits of the case. We are faced with the fact that over 7,000 general practitioners have changed their minds as a result of the concessions made by Mr. Bevan—and the fact that over 2,000 have not troubled to vote. It is possible that on further reflection more general practitioners will consider that while they have not gained all the points they sought the promised Amending Act and other concessions made by Mr. Bevan will provide them with an opportunity to practise their profession as independent men and women.

On the assumption that the Representative Body agrees that collective opposition is now out of the question it may decide that the best thing for the B.M.A. to do is to co-operate with the Minister of Health in trying to make the Service workable, to press for satisfactory terms and conditions of service for all sections of the profession, to be active in securing satisfactory Regulations, and to respond willingly to the Minister's invitation to assist him in framing the new Amending Act. If the B.M.A. pursues some such course in the interests of those who are prepared to serve under the new Act it will have no less an obligation to protect the interests of those of its members who decide to stay outside the Service. As there is a majority of Noes in answer to Questions A and B no one can pretend that the medical profession will enter this new Service in the enthusiastic manner which Mr. Bevan hoped would be the case. Apart from the deep antagonisms he stirred up in the medical profession by his treatment of the Negotiating Committee last December and his ill-advised utterances in the House of Commons in February, there is still a grave doubt in the minds of responsible doctors about the effect of a State medical service on the development of Medicine in this country. Whereas the voting in the plebiscite of February may have to some extent been influenced by a spirit of antagonism to the Minister of Health, we believe that this has had little influence in the results of the present plebiscite. Not only do medical men have serious doubts about the benefits to the public and to Medicine of a State medical service, but they have still graver misgivings about the possibility of starting such a Service in July in a way which is going to give the medical profession an opportunity to fulfil the promises made by the Government to the people of Britain. Mr. Bevan has very

few bricks at his disposal to build his new house, and the foundations of it even are still in the main only architect's plans. We foresee endless confusion in the administration of this new Service, and foresee, too, that the public will express their disappointment in no uncertain manner. Much of this hostile criticism will fall unjustifiably on the heads of the doctors. The medical profession will be able to meet this, and compose differences of opinion within its own ranks, if it continues to preserve unity within diversity. Only by remaining united shall we be able to influence the development of the new Service and the framing of the new Amending Act promised by the Government.

THE CENTENARY OF PUBLIC HEALTH

On Thursday morning H.R.H. Princess Elizabeth opened the Health of the People Exhibition organized by the Central Office of Information, and sponsored by the Ministry of Health, which is designed to commemorate the centenary of the passing of the first great Public Health Act. On Friday evening the Corporation of London held a dinner to celebrate this same centenary and also that of the appointment of their first medical officer of health, Sir John Simon. On another page we publish an article which discusses the conditions which led to the passing of this Act, the accomplishments of the men who held the stage in these stirring times, and the course of sanitary reform in the years which immediately succeeded the new measures.

That the social conditions of the first half of the nineteenth century cried for redress is well known, but the significance of the increasing depths of degradation into which the poor of our cities were sinking is perhaps less appreciated. Although the cholera of 1832 disturbed the equanimity of the complacent it still needed the fulminations of Chadwick, combined with the inquiries of several official and unofficial committees, to bring home the simple fact that wretched social conditions mean disease and death, and that in the long run they do not pay. Thirteen years after the first outbreak of cholera the Health of Towns Commission gave illuminating figures for certain industrial towns. In Preston, for example, in the four-hundred-odd houses which were surveyed people were sleeping on an average three to a bed, and in 84 instances four persons shared the same bed. Three years later the Metropolitan Sanitary Commission presented a similar catalogue of vile conditions. Bermondsey was intersected by open ditches of the most disgraceful character, and in the streets of Whitechapel there was neither sewerage, drainage, cleansing, paving, nor a good supply of water. It was soon evident that the remedy for such conditions would conflict with vested interests. It was probably only a Chadwick—careful, untiring, and self-sufficient—who could have brought these conditions home to the consciences of the landlords and owners. There was no house in the land which was not liable to suffer from the evils of sanitary conditions. The Queen's apartments at Buckingham Palace were reached through the common sewer; and at the time the footmen in the pantry suffered

constantly from sore throats, till it was discovered in 1844 that there were more than fifty unemptied cesspools under the Castle.

From before 1832 reform had been in the air, but in the case of the health of the people it was an unconscionable time in coming. The Public Health Act of 1848 made up for the delay. This was a truly great and pioneer measure. It consists of 152 sections, and in its printed form takes up 67 pages. The preamble expressly indicates that the intention of the Act is to place under one and the same local management such functions as sewerage, drainage, cleansing, and paving. It constituted a General Board of Health and gave it power to appoint officers. The Act was permissive, but if any area had not adopted it, and a certain proportion of the inhabitants petitioned the Board regarding local conditions, the Board had power to order a local inquiry and, if the result was not satisfactory, to enforce the Act in that district by an Order in Council. A Local Board was given power to appoint officers, such as a Surveyor, an Inspector of Nuisances, a Clerk, and a Treasurer. The Local Board might also appoint a qualified medical practitioner as an "officer of health." There are important sections dealing with sewerage. The Local Board had power to purchase the rights vested in any person for the making of sewers, and were responsible for the repair of sewers vested in them. The Act also deals specifically with the drainage of houses, with water closets in factories, public conveniences, the keeping of swine, the keeping of slaughter-houses, the regulation of offensive trades, the registration of common lodging-houses, and the prohibition of the use of newly built cellars as dwelling rooms. There was a similar prohibition of the construction of any vault or grave within the walls of or under any church built after the passing of the Act. The nuisance clause—referring to drains, water closets, privies, cesspools, and ash-pits—was advanced for its time, but the powers given for compulsory abatement were not adequate. From every point of view this Act, the centenary of which we celebrate this year, was an important and far-reaching measure.

We may refer briefly to the subsequent course of sanitary legislation in this country. There were of course many Acts of secondary importance, but these need not concern us. In 1866 the next principal Public Health Act was passed. This was not a permissive Act. As Simon expresses the matter, under it "the grammar of common sanitary legislation acquired the novel virtue of an imperative mood." By 1875 many Acts had been passed, and in that year all these were consolidated in the great Public Health Act, 1875. This was the long-abiding charter of health administration. It was not until 1936 that consolidation was again effected, and the Act of that year is still in force.

Turning to the other side of the picture, the translation of legislation into the day-to-day practice of the principles of sanitation, Dr. Underwood's article (p. 890) stresses the greatness of Simon in this field. Fortunate indeed was the City of London to acquire his services. At this time Duncan in Liverpool and Simon in London were the only two health officers in the country, and each in his own way was labouring, almost personally like a Hercules, to

cleanse the Augean stables of his area. It was eight years before medical officers of health were appointed for the vestries of the Metropolis, and later still for the country generally. The record of vital statistics shows what was achieved by these men in the succeeding years. At first the duties of these officers lay mainly in the field of sanitation, but from the days of Duncan and Simon, too, it had always been the function of the medical officer of health to deal in expert fashion with outbreaks of epidemic disease. This function could have been carried out only by a man qualified in medicine. As the years passed other clinical functions came within his field; to the supervision of tuberculosis was added the care of the mother, the school-child, and the infant, and in recent years cancer and rheumatism were tending to come under the jurisdiction of the health officer. Mr. Neville Chamberlain's Local Government Act, 1929—whose sole serious drawback was that it lacked the now by no means novel virtue of an imperative mood—enabled enlightened authorities to add to their responsibilities the maintenance and development of many large hospitals; and the medical officer of health had at last come into his own. His responsibilities now embraced the prevention and treatment of all diseases afflicting the seven ages of man.

The medical officers of health will regard these celebrations with pride—but pride mingled with regret and disappointment. Our legislators have seen fit to divorce hospitals from the health services, and once again the nation is faced with dual health administration. Yet the present generation of medical officers will look back with pride to the achievements of those men who in a true pioneering spirit shaped the public health service of this country to the great benefit of the health of the people of Britain.

HISTAMINE

It is becoming increasingly clear that drugs act by imitating or modifying the effect of substances which are ordinarily present in the body. The simplest illustration of this is the similarity between the drug ephedrine and the naturally occurring adrenaline. A large number of drugs imitate or modify the action of acetylcholine; they include muscarine, pilocarpine, arecoline, physostigmine, nicotine, and atropine. There is, in addition to adrenaline and acetylcholine, a third naturally occurring substance which like them is capable of producing dramatic effects in a moment—this is histamine. The function of this substance, unlike that of the first two, remains undiscovered, and we still think of it mainly as something toxic, which the body might well be without. In the lecture which is published in this issue of the *Journal* Prof. J. H. Gaddum has brought together all the clues which are available at the moment to those engaged in solving this riddle, and his analysis will be of the highest value to those working in this field.

It used to be thought that histamine was mainly produced in the lumen of the intestine, where bacteria made it from the amino-acid histidine by decarboxylation. It is true that some bacteria contain an enzyme which can carry out this change, but they do so only in an acid medium, about pH 5,

and not in the alkaline intestine. Indeed, only when the bacteria have adapted themselves to an acid surrounding are they found to contain the enzyme. A further reason for regarding the intestine as an unimportant source of histamine is the fact that large doses of the substance have little pharmacological effect when taken by mouth; they are conjugated either in the lumen or in the wall of the intestine.

Gaddum discusses the formation of histamine and describes the important work carried out by Dekanski, who investigated the amount of histamine in mice. If a mouse is anaesthetized and then immersed in hot water the quantity of histamine in the animal is doubled in the following hour. The new formation appears to occur in the skin. Feldberg and Kellaway observed the discharge of histamine from perfused lungs produced by various agents and drew up a balance-sheet of the amount disappearing from the lungs and that appearing in the effluent; they obtained no evidence of new formation. According to an attractive theory put forward by Rocha e Silva, histamine is combined in the tissues in a peptide linkage between the $-NH_2$ group and the $-COOH$ of lysine and arginine: the link is split by trypsin, with the setting free of histamine. The curious fact that the pain of a nettle-sting is caused by the simultaneous presence of histamine and acetylcholine has recently been demonstrated by Feldberg and Emmelin and is commented on in an annotation on another page. This action can be no coincidence, and must indicate a relation between the formation and function of the two substances.

If the body is flooded with histamine a large amount is excreted in the urine, but the enzyme histaminase is chiefly responsible for its removal. It has repeatedly been observed that there is a very great increase in the amount of this enzyme in the blood in pregnancy, which is believed to be due to production of histaminase in the placenta.

The best-known aspect of histamine at the present time is, however, the use of antihistamine drugs like "anthisan," "antistin," "benadryl," and others. One of the curious features of these substances is their apparent dissimilarity of chemical structure, which is so great as to suggest that their action cannot be related to their structure. Gaddum has made an interesting attempt to show how this difficulty may be overcome.

On other pages we publish articles on the clinical use of two of these compounds. Dr. J. Overton describes the use of antistin in skin conditions and Dr. N. Southwell the results of a trial of anthisan for asthma and hay-fever. Dr. Southwell's account is in some respects a model of how an investigation of this kind should be conducted. He furnished himself in the first place with dummy tablets as well as with tablets containing anthisan, and when he began to treat his patients he used the dummy tablets for the first two weeks in nearly all. He made the interesting observation that two patients with asthma of long standing found themselves notably benefited by these dummy tablets. The general method of the trial, which was carried on for eight weeks, was to grade each patient on his previous asthmatic history, and then to regrade him each week according to the severity of his attacks in the previous week. The grading consisted in allotting him a number from 1–6. At the end of the eight-week period the average weekly grade

number while taking the active preparation was available for comparison with the average weekly grading figure while taking the dummies. Needless to say the patients did not know whether they were receiving the real tablets or not.

The outcome of the trial was quite clear. Dr. Southwell found that anthisan—in a series of 27 patients—was of no benefit whatever in asthma, but that it was strikingly beneficial in hay-fever as shown in each of 15 patients. This investigation is an example of how a clinical trial can be made objective and quantitative, and it will well repay careful study by those faced with similar problems.

SURGEONS IN CAMERA

At a meeting of the Fellows of the Royal College of Surgeons held on April 28 three resolutions criticizing the National Health Service Act were passed. We observed in a recent leading article that it was desirable that the views of the Fellows of the Colleges on the National Health Service Act should be known. The Fellows of the Royal College of Physicians have already expressed their collective opinion in the two resolutions recently passed by the Comitia. Unfortunately the meeting at the College of Surgeons last week was held in secret and we were prevented from reporting it; a similar meeting a year and a half ago was open and was reported. The President of the College has, of course, the right to withhold an account of the meeting and to prevent publicity being given to the resolutions passed, which will presumably be considered at the next meeting of the Council of the College. But when between 200 and 300 Fellows meet at their own request to discuss such a serious matter as the National Health Service Act, and define their attitude to it in carefully considered resolutions, it would seem to be of the first importance that the medical profession at large should know the views of these distinguished men. The medical profession has urged upon the Minister of Health the need for free expression of opinion on all aspects of professional life and work in the new health service. It is regrettable that for the Fellows of the Royal College of Surgeons freedom of expression is to some extent curtailed by the withholding of their views from the rest of the medical profession. It is hoped that the Council of the College may remedy this by making public fairly soon the three resolutions passed on April 28. No good can come from concealing differences of opinion, and it is plain that consultants and specialists are sorely perplexed about their future under the National Health Service Act. This found expression in a resolution passed at a meeting of consultants in London two weeks ago. The Spens Committee's recommendations for consultants are not yet known, and Counsel's opinion (*Journal*, May 1, 1948) shows that many problems remain to be solved if consultants are to be able to work under the Act with anything like a contented mind.

THE ROYAL ACADEMY

In the age of statistics are there any to say how many visitors will be likely to visit the Royal Academy this year? It may be safe to say, quite unscientifically, that on the whole the medical profession is too busy for such pastimes as art appreciation, although it is true that there are a number of notable amateur artists among them. However, those who go to Burlington House this spring will have the

pleasure of seeing Henry M. Carr's competent painting of the Council of the Royal College of Surgeons of England (279), which takes its place among the more formal exhibits. There is a portrait (467) of Miss Elizabeth Bolton, C.B.E., M.D., late Dean of the Royal Free Hospital School of Medicine, and here the artist, William Dring, has made bold use of the colours of the robe in a lively and penetrating study. E. Roland Bevan contributes a forceful bust of Sir Alexander Fleming, and Maurice Lambert an interesting and lifelike full-length portrait of Viscount Nuffield, the model of a statue to be executed in bronze for Guy's Hospital.

If doctors can put aside their Gray's *Anatomy* they may take some pleasure in André Dunoyer de Segonzac's masterly composition "Bathers" (663). In the same room Leslie Cole's "Seated Figure" (706) may tempt them to obstetric speculations. The psychologists among them, noticing the high incidence of vitamins in the subject matter of the smaller exhibits, may discover anew how emotion is deepened when the object becomes comparatively inaccessible, for among the most delicate colour harmonies and most painterly studies in the exhibition can be numbered Nancy Meilor's "The Midday Meal" (12), Alec Bailey's "The Flour Sack" (58), Robert Hurdle's "Round Table: Still Life" (268), and Margaret Noakes's "Still Life" (435).

In a more serious mood psychologists may also study the moving portrait of the late Mr. J. G. Winant (333), in which the artist, James Gunn, has caught behind the simple and rugged exterior a great depth of suffering.

"STROKE A NETTLE"

Anyone who is sufficiently provoked by the stinging nettle to wish to find out the cause of his discomfort will be able, thanks to N. Emmelin and W. Feldberg,¹ to obtain nearly a complete answer. The statement that the active principle of the nettle was formic acid has repeatedly appeared in print and become part of the lore belonging to the plant. It now appears that the juice of the nettle does not contain this substance in any measurable quantity. The facts are both more interesting than the fiction and more in keeping with contemporary biochemical research. It has been ascertained that the fluid in the hair of a nettle contains one part in a hundred of acetylcholine and between one part in five hundred and one part in a thousand of histamine. In the case of the former, the content of individual hairs could be pharmacologically estimated. Ten hairs from a stalk gave values ranging between 0.02 and 0.4 millionths of a gramme, with an average of 0.108. Hairs from the upper surface of leaves contained only about one-third as much. In so far as histamine is concerned it had been assumed in advance, not unreasonably, that the sting of a nettle hair would prove to be merely one more stimulus for the release of this substance from human tissues. Instead, the histamine came from the nettle, although it was necessary to pool the contents of some 15-30 hairs to obtain a measurable effect. Further, it was established by tests on human subjects that both the acetylcholine and the histamine are needed to provoke the typical reaction. Neither separately can produce the equivalent of a natural "sting." On the other hand indications were also obtained that nettle-hair juice produces a more marked effect than would be expected from its content of these two substances alone. It is suggested, therefore, that there is probably a third active principle, still unidentified but, not formic acid.

¹ *J. Physiol.*, 1947, 106, 440.

ISOLATION OF ANTI-PERNICIOUS-ANAEMIA FACTOR

Ever since the discovery by Minot and Murphy in 1926 that pernicious anaemia responds specifically to treatment with liver attempts have been made to isolate the responsible active principle. For many years it was believed that it was a member of the vitamin B complex, though Castle,¹ writing in 1945, could not identify it with any of the known members of the group. When Spies and his colleagues² found in 1945 that folic acid, which occurs in liver, restores the blood to normal in pernicious anaemia it was at first suggested that this might be the long-sought anti-pernicious-anaemia principle of liver. This view could no longer be held when it was shown that folic acid, unlike active liver extracts, failed to prevent the neurological complications of pernicious anaemia; indeed, some workers claimed that it appeared to precipitate them in certain patients. The anti-pernicious-anaemia factor of liver is also many thousands of times more potent than folic acid. Thus Clark³ has calculated that, although 10 to 20 mg. of folic acid is the average daily dose needed for the initial treatment of pernicious anaemia, the maximum amount of it present in a curative dose of liver extract is of the order of 0.02 to 3.7 μg —a 5,000- to 20,000-fold difference.

In 1942, three years before the isolation of folic acid, intensive research was begun by a group of workers in the Merck laboratories in America to isolate the anti-pernicious-anaemia factor from liver. After six years they now announce the preparation of small amounts of the factor in a pure crystalline form.⁴ As the new factor is a member of the vitamin B complex, and as the last member to be named was B₁₂ (later shown to be identical with folic acid), the American workers propose that the new factor be called vitamin B₁₂. The progress of the work was materially hastened by the discovery of Shorb⁵ that a factor (LLD) required by the organism *Lactobacillus lactis* Dorner is present in refined liver extracts in concentrations bearing an almost linear relationship to the unit potency of the extracts used in the treatment of pernicious anaemia. It was suggested that the LLD factor might be the therapeutically active principle in these extracts. Intensive purification of clinically active liver fractions resulted in the isolation of a crystalline compound active for the growth of *L. lactis* and for the treatment of pernicious anaemia in relapse. This was vitamin B₁₂, which in doses of 3 to 10 μg , produced a prompt increase in the circulating reticulocytes, red cells, and haemoglobin in patients suffering from pernicious anaemia.⁶ The haemopoietic activity of this preparation is thus 7,000 to 8,000 times that of folic acid. The discoverers believe that 1 μg . may be approximately equivalent to 1 U.S.P. injectable unit of liver. Clinical work with vitamin B₁₂ has been hampered by the small amounts available.

During the last two years British workers have also been active in this field. As we reported in last week's issue of the *Journal*, Dr. E. Lester Smith,⁷ of Glaxo Laboratories, describes in a recent issue of *Nature* the preparation by repeated chromatography of a gramme of two red pigments from four tons of proteolysed liver. The preparations are active in pernicious anaemia in doses of 20 μg . and, what is even more interesting, they are effective in

the treatment of subacute combined degeneration of the spinal cord. Neither of Smith's pigments is identical with the vitamin B₁₂ of the Merck group, since they are both amorphous and weight for weight are not quite so active clinically. Further developments are promised on both sides of the Atlantic, and they will be awaited with interest.

NEUROSIS AND RELIGIOUS DENOMINATION

Between thirteen and fourteen thousand Service men were admitted to the Sutton Emergency Hospital during the six years September, 1939–September, 1945: 9,354 men went into the neuropsychiatric wards and 4,202 into the general wards. Slater¹ has classified these patients by religious denominations. The classification was based solely on the men's statement given as a routine on admission to hospital. Over 70% belonged to the Church of England, and the ratio of admissions to the psychiatric wards to admissions to the general wards of men of this denomination was taken as a standard to compare with other religious groups. No denomination had a significantly lower ratio than that of the Church of England, all the significant differences being in those groups which had a greater tendency to neurosis. It might be mentioned, however, that in the case of the Church of Scotland the ratio was 0.775, but statistical analysis showed that this was not a significant result. The ratios of the groups having a significant difference were: Roman Catholics, 1.250; Methodists, 1.386; Salvationists 2.843; Jews 5.338.

The interpretation of these figures can only be a matter of speculation, but Slater suggests that men of a neurotic disposition may find a particular denomination or religion attractive—for instance, the Salvation Army is not unwilling to gather in people with an irregular social record, among whom a high incidence of neurosis might be expected. The Jews are, however, in a different category, since nearly all the men were born into this faith and conversions to the creed are negligible. The Jews were unique among all the religious groups in showing a progressive rise in the incidence of neurosis during the course of the war. The number of admissions of Jews to the neurotic wards rose from 1.3% to 6.7% during the six years. This rise was not influenced by the recruitment of foreign refugees into the Army, all foreign nationals being excluded from the analysis. The author suggests that perhaps Jews possess a stronger than average attachment to their immediate domestic circle and the society of their fellows and that Army life causes a relatively greater strain.

PROCEEDINGS OF THE ANNUAL MEETING

The Council of the B.M.A. has decided to publish in a separate volume the papers read before the Scientific Sections of the Annual Meeting to be held in Cambridge in June. Just before the war it was resolved that the Opening Papers read to the Sections should be published in the *Journal* at the discretion of the Editor. As the paper for the *Journal* is still strictly rationed, and as it is possible to find space for only a proportion of the original articles submitted in the ordinary way, it will be possible to print in the *Journal* only a few of the papers read at the Annual Meeting. But all contributions will be put on permanent record in the *Proceedings*. So that plans may be made for printing the *Proceedings* it is to be hoped that those who are reading papers at Cambridge in June will as soon as possible send them to the Editor of the *Journal*.

THE CENTENARY OF BRITISH PUBLIC HEALTH

RISE OF HEALTH LEGISLATION IN ENGLAND AND IN LONDON

BY

E. ASHWORTH UNDERWOOD, M.A., B.Sc.
M.D., D.P.H., F.L.S.

Director of the Wellcome Historical Medical Museum

On May 7 the Corporation of London commemorated the centenary of the first Public Health Act and of the appointment of Sir John Simon as first Medical Officer of Health for the City. Although nowadays civic hospitality must be on a modest scale, the guests and the commemoration dinner were fully representative of the leaders in health legislation and administration and in the various departments of preventive medicine. The year 1848—the zero year of public medicine in this country—was marked by several events of the first importance, and this celebration, coinciding as it did with the opening of the Health of the People Exhibition, which has been arranged by the Central Office of Information and is sponsored by the Ministry of Health, was intended to commemorate all of them. This article is written as a reminder of these epoch-making events and as a tribute to the men, far-seeing beyond their time, who shaped their course.

The Prelude to Legislation

The cholera epidemic which ravaged this land in 1831-2 caused a profound but unfortunately temporary stirring of the social conscience of the people. The importance of this outbreak, and its effect on the minds of the men and women who feared its terrors, can hardly be overestimated. This disease of the Far East, which had hitherto been of interest only to those who had practised there, first reached this country in October, 1831, and from then until the end of 1832 it overran Great Britain and Ireland, causing the death of 31,400 persons in Great Britain alone. In a recent communication I gave a table showing the distribution of these cases in time (Underwood, 1948a), and it will be seen there that small towns appear in company with the great cities in this roll of dishonour. In 1833 there was a recrudescence of cholera in London, when the metropolis had 1,454 deaths, and there were also a few scattered minor outbreaks in other parts of the country. But for all practical purposes cholera had burnt itself out, and, although the fear of it continued to haunt the people, there was no further outbreak until the next great epidemic of 1848-9. The intervening period of sixteen years saw an armed truce between the forces of disease, filth, and squalor on the one hand and the powers which were being gradually assembled to combat them. No mean difficulty confronts anyone who sets out to give a few examples of the prevailing conditions. The reader may think that a finger of scorn is being pointed at a certain locality, whereas all the contemporary reports show that there was nothing to choose between any of them. With this proviso in mind a fairly typical example may be given here. Baker (1833) described some of the appalling sanitary conditions which were found in the township of Leeds. In three parallel streets, housing about 386 persons, the sanitary conveniences consisted of two small privies, which were in such a state as to be totally unusable. From the privies in one end the accumulated filth of thirty years was removed by order of the Commissioners. Seven years after this cholera epidemic in Leeds the streets had again become so full of excrement, filth, and refuse of every description that their surfaces were far above their original level. It is small wonder that no official action was at last taken in this country generally until it should have shown itself primarily in the abatement of sanitary nuisances. The broader conception of health measures began later, and evolved almost entirely in the mind of one man—Sir John Simon.

The cholera epidemic of 1831-2 had two results of the first importance. In the first place it showed the urgent need for sanitary reform in town and country alike. In the second place it gave rise to an event which demonstrated that the control of medical action against a grave

epidemic disease, could be directed by a central government department. I refer to the Royal Proclamation of June 2, 1831, which announced the formation of a consultative Board of Health, of which Sir Henry Hallford, the President of the Royal College of Physicians, was elected chairman (1831-1897). It was a matter for congratulation that this Board was appointed before cholera actually reached our shores. But it had no powers of compulsion, though the Government did subsequently issue certain Orders in Council implementing some of the Board's recommendations.

Though educated men and women felt the stigma of the conditions in which the population was dwelling, the stimulus to effect improvements was lacking, and the offensive weapons against the powers of darkness were not yet forged. The real awakening of the public conscience took place during the decade 1838-48. This was the era of Chadwick and Southwood Smith, of Neil Arnott and James Phillips Kay (Sir J. P. Kay-Shuttleworth). The necessary action came through a demand for the reform of the Poor Law, and it is worth while noting that ten years were to elapse between the recommendation for the introduction of the necessary legislation and the actual passing of the Act.

Sir Edwin Chadwick

Edwin Chadwick (1800-90) was one of those men who stumbled almost by accident into their life's work. As a young man he studied for the Bar, but when he was 29 years old he wrote an essay on *Preventive Police* which was seen by Jeremy Bentham. The two men met and appear to have got on very well together, since Chadwick went to stay with Bentham at the latter's house in Queen's Gate. The association continued until Bentham's death in 1832, and during the intervening period Chadwick was called to the Bar, carried out many first-hand investigations into the social conditions of the poor in London, and finally renounced the Bar as a profession. The reason was his appointment in 1832 as an Assistant Commissioner to the Commission which had been set up to inquire into the Poor Law system. In the following year he was promoted to be a Commissioner, and in the same year he was also appointed as one of the three Commissioners on a Royal Commission to examine the treatment of children in factories. In 1834 the Poor Law Commission issued its Report, and this led to the Poor Law Amendment Act and the formation of the Poor Law Board with Chadwick as secretary.

Chadwick really opened his campaign against the evils of defective sanitation four years later, when the Poor Law Board sent a famous letter to Lord John Russell, the Home Secretary, in which they pointed out that some of the most important charges on the poor rates are those "which are caused by nuisances by which contagion is generated and persons are reduced to destitution." Later on the Commissioners said: "We have eagerly availed ourselves of the opportunity of making the present Report, to submit to your Lordship the urgent necessity of applying to the Legislature for immediate measures for the removal of these constantly acting causes of destitution and death. All delay must be attended with extensive misery, and we would urge the consideration of the fact that in a large proportion of cases the labouring classes, though aware of the surrounding causes of evil, have few or no means of avoiding them, and little or no choice of their dwellings."

Sir Edwin Chadwick, 1800-90

Southwood Smith

The Commissioners attached to their letter two reports which had been specially drawn up by their medical inspectors. The first was a joint report by Dr. Neil Arnott and Mr. James Phillips Kay, *On the Prevalence of Certain Physical Causes of Fever in the Metropolis*. Neil Arnott (1788-1874) was at that time a well-known London physician and was a physician-extraordinary to the Queen. In 1827 he wrote a popular textbook on physics, and his practical inventive capacity found expression in such well-known devices as Arnott's ventilating valve, his smokeless fireplace, and his water-bed. Arnott was a founder and an original member of the Senate of the University of London (1836). Sir J. P. Kay-Shuttleworth (1804-77) became secretary to the Manchester Board of Health, and was the author of a technical work on asphyxia. He may be regarded as the founder of English popular education, and he was a joint founder of Battersea Training College.

More intimately connected than either of these men with the succeeding progress of legislative public health was the author of the second report attached to the Board's letter—Thomas Southwood Smith (1788-1861). Munk gives a sympathetic summary of his life and work (Munk, 1878). Smith was at first a dissenting minister in his native Somersetshire, and he then studied medicine at Edinburgh. During this period he wrote his *Divine Government*, which was praised among others by Byron, Moore, and Wordsworth. Southwood Smith was for twenty-four years physician to the London Fever Hospital, and he was therefore well qualified to carry out medical work for the Poor Law Board. This second report to which I have referred was entitled *On Some of the Physical*

Causes of Sickness and Mortality to which the Poor are Particularly Exposed. It emphasized the fact that, while in the districts of London occupied by the wealthier classes streets had been widened, drainage improved, and nuisances removed nothing whatever had been done to effect similar remedies in the poorer districts. He gave telling figures to emphasize the results. Southwood Smith was later prominent in the formation of the Health of Towns Association (1839) and of the Metropolitan Association for Improving the Dwellings of the Industrial

Thomas Southwood Smith,
1788-1861

Classes (1842). His essay (1832) in the *Westminster Review*, which was later reprinted as a pamphlet entitled *The Use of the Dead to the Living*, led to the passing of the Anatomy Act. He wrote also on fevers and a popular work entitled *The Philosophy of Health* (1835-7). To anticipate, Southwood Smith became the medical left hand to Chadwick's right. When the General Board of Health was constituted in 1848 Southwood Smith became its medical member, and he remained in this office until the Board was dissolved in 1854. It is well known that he was Jeremy Bentham's private medical attendant: that Bentham left his body to Smith for dissection; and that Smith delivered an oration over the body on June 9, 1832, before starting the dissection.

Chadwick's Harvest Years

The letter from the Poor Law Board to the Home Secretary led to many debates in Parliament, especially in the House of Lords, and in 1842 the Government published three volumes of reports. The third volume was entitled a *General Report on the Sanitary Condition of the Labouring Population of Great Britain*. It was written by Chadwick, and was published (1842) in his name. He recommended, *inter alia*, efficient drainage, the removal of refuse, and the improvement of water supplies. He also made the prophetic statement that "it would be good economy to appoint a district medical officer independent of private practice, and with the securities of special qualifications and responsibilities to initiate sanitary measures and reclaim the execution of the law." Chadwick's recommendations were

substantially confirmed by a Royal Commission which reported in 1844 and 1845 and gave thirty detailed recommendations proposed for the local authorities. The chief momentum for all subsequent action came from this report of Chadwick's and from the Report of the Health of Towns Commission which soon followed.

The years 1845-7 saw the placing on the Statute Book of a number of minor measures—dealing with markets and fairs, gas-works, waterworks, and cemeteries—which formed the background to the Act of 1848. This was the Public Health Act, which received the Royal Assent on August 31. This is the charter which is being celebrated this year. Another important measure was the Nuisances Removal and Disease Prevention Act of 1848. A metropolitan Act of 1849 made similar provisions for London as did the Public Health Act for the rest of the country. (This London Act did not apply to the City, which was dealt with by the City Sanitary Act.) The new legislation established a system of summary jurisdiction against the chief health nuisances. It further created a General Board of Health, which was to continue for five years. Chadwick was appointed one of the three Commissioners, along with Lord Carlisle and Lord Shaftesbury. A little later Southwood Smith also became a member of the Board. The addition of Smith did not occur until 1850, and on the authority not of a Public Health Act but of the Metropolitan Interments Act. This led Henry Wyldere Rumsey (1856) to write of the whimsical experiment which had been tried of appointing three non-medical authorities—two lords and a farmer—to preserve the health of the living, and then, after a year or so of doubtful success, of calling in a physician to bury the dead.

Under the driving force of Chadwick the new Board got rapidly to work. By 1853 the Board had been memorialized from 284 places for application of the Act, and had applied the Act in 182 places having in all more than two million inhabitants. The Board introduced measures regarding common lodging-houses, and made recommendations regarding burials in towns. In the field of water supply it straightway developed grandiose ideas. It proposed to centralize all the water undertakings of London, and there is evidence that it intended to be itself the owner and director of this organization. There is no doubt that this first General Board of Health laboured from the start under three drawbacks. In the first place, it was not represented in Parliament by a Minister of the Crown, so that criticism of its activities could not be dealt with effectively as soon as it was uttered. Secondly, it had no whole-time engineering inspectors. Its technical experts were engaged in the locality where they were to be temporarily employed, and in this way abuses were apt to be met with. The third drawback was—Mr. Chadwick. As a pioneer he had been admirable, but the very qualities which made him a great pioneer rendered him rather intolerant as an administrator. If there were vested interests which might be trod on Chadwick trod on them with all his weight. The result could not have been long in doubt. In 1854 the General Board of Health was terminated and a new Board was constituted in its place. Chadwick retired on a pension of £1,000 a year. His "official" life was ended, but during the next thirty-five years he continued to wage an unofficial war on dirt and disease. As an administrator Chadwick was impatient of results. In Sir John Simon's words, "he probably hoped to achieve in a few years the results which not ten times his few years could see achieved; and where others on all sides were hanging back, his ardour seemed ready to undertake the work of all."

In passing, it should be said that the General Register Office had been established in 1836, and that William Farr had been appointed as Compiler of Statistics in 1839. Farr founded a new science. In the telling phrase of Simon, he was "a master of the methods by which arithmetic is made argumentative." One has either to write much about him, or exclude him of design, and honourably. In this short note I have no choice. His work was an essential weapon for his contemporaries and many who followed later. To those who are interested I would recommend the sympathetic account of his mind and work which Prof. Greenwood (1948) recently published.

The Rise of the Medical Officer of Health

I have already quoted Chadwick's words recommending that it might be worth while to appoint whole-time medical officers

independent of private practice. An Act of 1847—the Towns Improvement Clauses Act—not only dealt with improvements in paving, draining, cleansing, and lighting, but gave power to large towns to appoint such medical officers. Liverpool had already anticipated this authority, since it had by a local act of 1846 sought and obtained power to appoint a medical officer of health. Dr. William Henry Duncan—the first medical officer to be appointed in Great Britain—had taken up office on Jan. 1, 1847. Duncan was a most conscientious and capable officer, and in Liverpool he had to deal with incredible problems of overcrowding, bad sanitation, gross immigration, and constant outbreaks of disease. If his reports did not have the classic ring of those of Simon, he was nevertheless a great medical officer who demands our respect. In another communication I deal more fully with his work (Underwood, 1948b), and Prof. Frazer, of Liverpool, recently published a biography of Duncan which was long overdue.

The City of London followed swiftly the example set up by Liverpool. The City Sewers Act of 1848 was to become operative from Jan. 1 of that year. It contained important provisions relative to the sanitation of the City, and gave power for the appointment of a medical officer of health. In October, 1848, Simon took up this office.

Sir John Simon (1816-1904)

The holder of this important post was a young man who was well fitted by his training and general intellectual ability to fill it with dignity. John Simon, born in 1816, was the sixth of fourteen children, and was more than half French. At 16 years he studied in Germany for a year, and in 1833 he was apprenticed to the surgeon Joseph Henry Green. Qualifying

Sir John Simon when Medical Officer of Health, City of London, 1848-55

in 1838, Simon decided on a surgical career, and during the next ten years he held posts of some importance as a surgeon and as a pathologist. For his pathological work he was elected to the Royal Society at the age of 29, though the mesh was much wider then than it is now. In his spare time he studied metaphysics, Oriental languages, and art.

Simon held the post of medical officer of health to the City for seven years. When the new General Board of Health was formed Simon became its first medical officer

in 1855. Shortly afterwards the Board's duties were taken over by the Privy Council, and Simon served this body well for thirteen years. Supported by a brilliant team of colleagues, he built up a system of public health which was the envy of the world. He was in effect preaching the importance of public health as an administrative entity, and the creation of a Ministry of Health. In 1871 his hopes were dashed when various heterogeneous departments were amalgamated to form the Local Government Board. Public health interests were now constantly subordinated to the demands of the Poor Law, and the advice of medical officers to that of lay administrators. In 1876 he asked leave to retire, and the country thus lost one of its ablest administrators while he was still an active force. After his retirement Simon lived for 28 years—the recipient of many honours and the friend of many celebrities, including Ruskin and George

Simon at the City

Simon's appointment as medical officer of health to the City of London in 1848, as Simon very soon found.

He came to be regarded at Whitehall as an officer available for the general public service, and he served on several important Government bodies. On his appointment Simon at once came to an arrangement with the Registrar-General whereby he was provided each Monday with the death returns for the City for the previous week. He instituted a system of weekly inspections, with a follow-up of all nuisances. In the few years of his tenure of the office enormous improvements were effected in drainage, water supply, the abatement of nuisances, in scavenging, and in general cleanliness. He says himself that "at a time when cesspools were still almost universal in the Metropolis, and while, in the mansions of the west-end they were regarded as equally sacred with the wine-cellars, they had been abolished, for rich and poor, throughout all the square mile of the City."

The five annual reports which Simon wrote while he was in the City are classics of public health administration. In his first report he pointed out that the mortality was about twice the mean mortality of surrounding districts. He stated that some thousands of houses in the City still had cesspools, and he described their evils in eloquent language. In dealing with water supply he laid down the postulates that every house, and every floor of a tenement, should be separately supplied; that every privy should have a sufficient supply; that every court should have a standcock; and that the supply should always be uninterrupted. He stated that there were 138 slaughter-houses in the City, and in 58 of these slaughtering occurred in vaults and cellars. He was convinced that both slaughter-houses and other offensive trades should be excluded from the Metropolis. He not only condemned further burial in vaults but recommended the burial outside the City of coffins already deposited in vaults. In connexion with unfit and unsanitary houses he struck a modern note immediately: the removal of walls is, he says, only a palliative, and the best measure is the wholesale purchase of series of courts and the demolition of all the houses in them. In dealing with the social conditions of the poor he expresses his belief in the powers of education. Simon emphasized that the most important task which lay ahead was inspection, and he recommended the establishment of a whole-time staff of inspectors. Finally he said that he considered it indispensable that the authority should receive the largest and most accurate returns which could be procured of all sickness occurring among the poorer classes. A hundred years after he wrote these words these returns are still indispensable for both the statistician and the administrator—but they have not yet materialized. Simon's other reports followed closely on the lines of his first—emphasizing water supply in one year, cholera in another, as the occasion demanded. As examples of vigorous, fearless prose in official reports they can seldom have been equalled.

Epilogue

The events which I have inadequately described had a far-reaching influence in this country and abroad. The two men who were principally concerned were both young men when they entered the field, and both were pushed out of office while still in mature manhood. Simon qualified in 1838, and during the decade when Chadwick was at his prime Simon apparently showed not the slightest interest in what was going on in the field of sanitation and public health. Yet in 1848 he took over the most important area in the country, wrote a classic report, and immediately laid down plans of action and procedure which were to be followed by other health administrators for many years to come. While during these centenary celebrations we will honour them and their only slightly less gifted colleagues, our thanks are also due to the enlightened members of the City Corporation in 1848-54—for these were the men who first really accepted Chadwick's principles and who gave Simon the opportunities which he so quickly grasped.

The work carried out by staff of the British Medical Association for the purpose of obtaining a plebiscite of the medical profession on the matters set out in column (1) of the above Tables was directed and supervised by our representatives continuously from its start on 16, April until 4, May, 1948. The completed plebiscite forms received during that period were examined only by our representatives and by staff of the Association working under our supervision and under pledge of secrecy and were retained under our control from the time of their receipt at B.M.A. House until their destruction in the presence of our representative on 4, May, 1948.

We satisfied ourselves by appropriate tests

(1) that all reasonable steps were taken to furnish a plebiscite form to every registered medical practitioner either resident in Great Britain (but not Northern Ireland) or serving in H.M. Forces at home;

(2) that the figures set out in the foregoing Tables I, II, and III are a correct summary and analysis of the replies received at B.M.A. House up to and including the second post on Monday, 3, May, 1948.

PRICE, WATERHOUSE & CO.
Chartered Accountants.

PLEBISCITE RESULTS, MAY, 1948

SOME IMPORTANT PERCENTAGES

All percentages are calculated to the nearest whole number. 50,514 Plebiscite Forms were sent to practitioners other than those serving in H.M. Forces. The distribution of practitioners as between England and Wales* and Scotland* is based on figures obtained from B.M.A. records.

		Question	Total Voting	Percentage Approving the Act	Percentage Disapproving	Not Voting	Of those who Voted	
							Approving	Disapproving
All civilian categories	Great Britain	A	77%	28%	49%	23%	36%	64%
	England and Wales*	A	78%	28%	50%	22%	35%	65%

† Excluding those of specialist status (covered by Group 1 B) but including practitioners holding B1, B2, and A appointments and Class I and Class III appointments under the Government's postgraduate scheme for ex-Service practitioners.

Reports of Societies

ENDOCRINOLOGY OF SCHIZOPHRENIA

In the Section of Psychiatry of the Royal Society of Medicine on April 12, with Sir DAVID HENDERSON presiding, certain experimental investigations of the endocrinology of schizophrenia were presented.

Dr. R. F. HEMPHILL said that the theories he put forward were advanced with the greatest diffidence. It was not his intention nor that of Dr. Reiss, who was associated with him in a research programme, to suggest that schizophrenia was an endocrine disorder, but from their work and that of others there was sufficient evidence to encourage research into endocrine relationships. The greatest single difficulty in research of this character was to find case material which was clinically homogeneous. An endeavour had been made to collect cases on account of their psychiatric similarity, but it was found that cases which had an apparently identical picture clinically might have dissimilar physiological patterns. The majority of the papers on the subject had dealt with the investigation of phenomena in isolation, such as oxygen consumption, liver function, and so on, and to add to the multitude of such investigations would contribute little to the problem. Therefore the present research had been directed to biological or endocrine indications.

In recent years pathological changes in the testes in schizophrenia had been studied. Biopsy specimens consistently showed an abnormal picture in schizophrenia. The speaker proceeded to describe a series of tests, but remarked how difficult the picture of inconstancy operated against biochemical research. It had been thought that schizophrenic

patients could be grouped into those of constant and those of inconstant physiological or biochemical patterns, but unless the patients were in the same stage of the disease or were suffering from the same conditions clinically much variation in the results was to be expected. If tests could be devised which would reveal constancy or inconstancy it should be possible to detect patients with similar patterns and subject them to extensive and detailed investigations.

Study of Ketosteroids

A special study was made of the ketosteroids for constancy and inconstancy as well as for information about endocrine activity. It was observed that their output increased after electrical shock treatment and leucotomy. After E.C.T. a sudden increase up to three times the upper level of normal had been seen; but it was still impossible to isolate from these results any particular pattern of variation, and it could not be said that the patients could be grouped according to constancy and inconstancy patterns. After further study a group of six chronic patients who had failed to respond to recognized treatments were chosen, first because they were regarded as incurable, secondly because it was possible to assess their clinical state by a mere inspection, and thirdly because the onset of their illness occurred in each case rather late in life, and thus it was hoped to avoid the variation of the endocrine changes in early adolescence. They were as nearly similar in health, nutrition, and clinical picture as possible, and were investigated under standard conditions. But although these patients were identical clinically the fractionated ketosteroids were not. Dr. Hemphill described one case in which treatment daily with testosterone brought about a remarkable clinical improvement. The patient, aged 33, who had scarcely spoken for eight

REPORTS OF SOCIETIES

MAY 8, 1948

years, and had been immobile, became active, talking and walking, and showed an increase in weight and growth of beard. Although this patient did not recover, he remained for a year in a state of partial remission, only relapsing if not treated with testosterone. The patient's state was not corrected but it was influenced, and it was reasonable to suppose that this single case there was a close relationship between the abnormal endocrine state and the clinical condition. Without biochemical control the empirical treatment of these patients would have produced the same result, but it would not have been possible to say why treatment succeeded in the one case and not in the others. One could not optimistically speculate that if the methods of analysis were sufficiently correct definite indications for treatment in many cases could be found; endocrine diseases were not simple, and might have to be corrected by the administration of more than one hormone. Nor was it known whether the successful result was due to the direct action of the hormone or to its effect on the hormone balance. The necessity of prolonged treatment had been stressed by other workers.

Another investigation related to thyroid function. A proportion of schizophrenic patients responded to thyroid treatment for a time, and many showed a tolerance of thyroid for a few weeks, but it was not clear whether these results were due to failure of reactivity or to some special property of the thyroid itself. Investigations had also been made concerning the physical development of schizophrenic patients, and these would be continued for five years and records of the measurements kept.

The speaker touched finally on puerperal schizophrenia. In such cases the pre-psychotic mental constitution was usually good and the physique normal, and this was the one form of schizophrenia which came under treatment within a few days or weeks of the onset of psychotic symptoms. The prognosis on that basis seemed likely to be favourable, but in point of fact the prognosis was probably the worst of all, and in his service there appeared to have been not more than two or three cases of puerperal schizophrenia which had made full remission. Puerperal schizophrenia should be an entity in the disease group and most acceptable to hormone investigation.

Other Investigations

Dr. M. REISS added a number of further points on investigation and described in more detail the experiments outlined by Dr. Hemphill. He said that it seemed clear that there was something decidedly wrong with the adrenal mechanism in these patients, sometimes a lowered, sometimes a heightened function. He described the difficulties of estimation of thyroid function in schizophrenia until there was worked out a modification of the method recommended by Dr. Russell Fraser and it was possible to determine in certain cases the protein-bound iodine. There were very few results to date, but, such as there were, they were in the same direction as the results with the ketosteroids. Very often there was a decrease of the protein-bound iodine, but sometimes a very considerable increase. Concerning the pituitary hormones, the problems were mainly those of method. It might be asked how an effect on the anterior lobe function could have an effect on the brain. From one-third to one-fourth of the total metabolism in the body took place in the brain, whose sugar reserves were more easily exhausted. Dr. Reiss added that nothing in fact was fewer tempting than to form hypotheses, particularly if facts were few and not contradicted, but it was much more profitable to leave any hypotheses and just to see what future developments would bring.

EPIDEMIOLOGY OF TRYPANOSOMIASIS

At a joint meeting of the Section of Comparative Medicine of the Royal Society of Medicine and the Royal Society of Tropical Medicine and Hygiene, held on April 21 under the chairmanship of Mr. R. E. GLOVER, a discussion took place on the epidemiology of trypanosomiasis in animals and man. Mr. J. CARMICHAEL said that tsetse flies were confined almost entirely to the continent of Africa. Generally speaking, the existence of domestic animals was incompatible with contact with the fly. The dwarf cattle of West Africa were apparently able to survive, and it had been claimed that this particular

breed was immune, but absolute proof of immunity had not been obtained even after ten years' work on the problem by the Agricultural Department in Nigeria. Large numbers of human beings in Africa were living in contact with the tsetse fly, and the question was whether the fly was infected with the human parasite and, if it was, why the disease did not occur. Even under epidemic conditions the percentage of infection was never very high. Why was it that over large parts of the area domestic animals were infected but not man? He could not help thinking that throughout Africa there must be a balance between trypanosomes and man, and that this balance was upset and an epidemic started as a result of some outside factor, environmental or nutritional. A great deal of fundamental knowledge was still lacking. During a sojourn in the West Nile many years ago he had noticed the occurrence of epidemics of drugs in the tsetse fly areas was a waste of time because the cattle were quickly reinfected. One of the most important factors in the epidemiology of trypanosomiasis, whether in man or animals, was the shifting character of the fly population. In Uganda, where he had first-hand experience for many years, the extension of the fly area recently had been most serious.

Dr. C. A. HOVER said that trypanosomiasis as affecting both man and domestic animals afforded one of the best examples of a common ground between medical and veterinary science. Both the epidemiologist and the protozoologist were faced with the same problem—detection of the source of infection and its control. The parasites supposed to be responsible for the chronic and acute forms of sleeping sickness were *T. gambiense* and *T. rhodesiense* respectively, but these two parasites were closely related and sometimes apparently identical. The question of reservoir hosts was highly controversial. From the epidemiological point of view trypanosomes found in animals in localities where the human disease was unknown were probably *T. brucei*.

In addition to epidemiological data, significant results thrown light on the problem had been obtained from observation on experimental infections in various animals. It had been demonstrated that *T. rhodesiense* could be maintained in cyclical transmission to antelopes and to sheep for about 1 year, in the course of which it remained infective for man. Similar observations on *T. gambiense* showed that it could be transmitted cyclically to goats and pigs for four years without losing its transmissibility to man. It was concluded that sleeping sickness various other mammals in addition to man constituted a source of infection, and that the relative importance of the human and animal reservoirs differed according to the type of distribution of the disease.

If it were proved that *T. brucei* were capable of establishing itself in man, both wild animals harbouring this trypanosome and domestic animals would have to be reckoned as dangerous sources of human infection. Apparently the chief factor which prevented *T. brucei* from originating from establishing itself in man was the trypanocidal action of normal human serum. In man was the trypanocidal action of normal human serum might occasionally lose its trypanocidal properties, as, for example, in some diseases of the liver and in certain types of avitaminosis, some workers maintained that human beings with such conditions might become susceptible to *T. brucei*. Further, exceptionally virulent strains of *T. brucei* might be capable of overcoming the trypanocidal action of normal human serum. According to this hypothesis, having thus established itself in man, *T. brucei* would gradually adapt itself to its new host, at first behaving like *T. rhodesiense*, which it had so many features in common, and would give rise to acute disease, and subsequently would acquire the characteristics of *T. gambiense*, giving rise to a mild or chronic disease. Although on theoretical grounds this appeared to be a plausible hypothesis, it could not be accepted unreservedly for several reasons. All attempts to infect human volunteers with *T. brucei* had so far failed, though in a case recently reported from the Belgian Congo a transitory infection had been produced. It had also been demonstrated that *T. rhodesiense* could be transmitted cyclically to infect man—in other words, without losing its power to infect man—in other words, without reverting to a form indistinguishable from *T. brucei*. It

might be concluded that *T. brucei* could not readily adapt itself to man unless it was transformed into *T. rhodesiensis*. It was reasonable to assume that this evolution had actually occurred in the remote past and might operate at present under exceptionally favourable conditions, the nature of which was not yet known.

In conclusion it might be noted that in addition to trypanosomes which were common to man and the lower animals, like the African and South American trypanosomes, there were a large number of cases on record showing that purely animal parasites could occasionally break the barrier of host restriction and establish themselves primarily in man. On one or two occasions human infection with the trypanosome of ungulates had been reported from Africa.

In the course of a short discussion Dr. J. T. EDWARDS mentioned with regard to non-tsetse trypanosomes the difference in susceptibility to infection of different species of animals. In India horses which became infected with a particular trypanosome almost invariably died, whereas cattle were highly resistant, though probably carriers. In the chemotherapy of trypanosomiasis in horses treatment had to be drastic, for if one surviving trypanosome were left in the animal there would be a relapse.

BACKACHE-SCIATICA SYNDROME

A joint meeting of the Liverpool Medical Institution and the Manchester Medical Society, held at Liverpool on March 4, discussed "The Backache-Sciatica Syndrome and the Intervertebral Disk."

Sir HARRY PLATT reviewed the stages by which our present knowledge of the pathogenesis of the backache-sciatica problem had been reached. During the past forty years the concepts of sacro-iliac and lumbo-sacral strain, the part played by lumbo-sacral skeletal anomalies, the intervertebral arthritis theory, and the contracted ilio-tibial band represented a sequence of clinical entities which had in turn been rejected in favour of the present-day view that the prolapsed intervertebral disk was a dominant lesion in sciatica. He referred to the many thousands of successful operations for the relief of backache-sciatica which had been carried out by neurological surgeons and orthopaedic surgeons both in Great Britain and the U.S.A. On the other side of the picture, however, was the experience of a not inconsiderable number of failures to demonstrate a disk lesion at operation. Moreover, extravagant claims had been made for the intervertebral disk as the only "reputable" cause of sciatica. Many now held that in the backache-sciatica syndrome extra-spinal lesions could be ignored. He reminded his audience that a large-scale survey of backache-sciatica patients in the Mayo Clinic had shown that cases of disk lesions were in the minority; and he quoted with approval the opinion of Love that the disk protrusion was the commonest *intra-spinal* cause of sciatica. This meant that extra-spinal lesions were not myths.

The differential diagnosis of sciatica could be approached by the recognition of five main causes: (1) pelvic visceral disease; (2) bony lesions of the lumbar spine, pelvis, and femora—these might be inflammatory lesions or new growths; (3) lesions of the spinal, pelvic, and hip joints—in this group the protruded disk had displaced sacro-iliac strain and vertebral arthritis as the dominant lesion, though sacro-iliac strain and vertebral arthritis were still real lesions, and in his experience sciatic pain was also a common feature in osteoarthritis of the hip joint; (4) central nervous lesions proper—for example, crural equine tumours; (5) "pseudo-sciatica," or fibrositis of the fascial, ligamentous, and muscular structures in the lumbar region, buttocks, and thighs. He believed that this type was increasingly important. The condition of fibromyositis might, of course, cloak an underlying arthritic state of the lumbar spine in which degenerative changes were likely to be present in the intervertebral disks.

Posterior Crural Pain

Dr. G. G. GIBBS, after agreeing that it was possible to distinguish the attack of sciatica—how much better a name than the term "lumbar sciatica"—from the non-committal "posterior crural pain," which might be due to neuritis, said that

it was impossible to prove it. A small disk rupture might have taken place even then. As for neuritis, it had proved too successful a diagnostic name. He thought that true neuritis in the proper inflammatory sense was a rare disease. With Mr. Kessel he had conducted a follow-up study of patients with sciatic "neuritis" seen earlier than five years ago. The unoperated series was small and replies were obtained from 26 patients. Of these two-thirds had continued to have attacks; three had been badly handicapped, and in the remainder the attacks had been of the remitting type with severe episodes only rarely.

This finding was in line with the Scandinavian reviews of close on 500 patients and lent little support to the contention that sciatica was commonly a transient and unimportant disorder. Yprehus (1947) found only 33.8% of unoperated cases able to do full work, while in Boysen's survey in 1947 only 21.1% were quite free from pain. Relapses in unoperated cases could be accounted for in three ways: (a) because there was from time to time a sudden further small protrusion of disk tissue; (b) because, the prolapse remaining unchanged, there were recurrent episodes of oedema or congestion; and (c) the tension caused by the hernia was intermittent because the disk popped in and out—a process he found very difficult to believe. He thought that the hernia caused pain by tension rather than by pressure on the nerve-root.

No disk protrusion had been found in only 8 out of 130 cases operated upon by himself or his assistants. The problem of alternative causes of sciatica was not as great as some suggested; nevertheless, the negative cases were important. Sufficient time had not yet elapsed for a clear picture to be formed of the after-histories of the patients with negative findings at operation. Patients from whom a disk had been removed were in the main either cured or had insignificant pain. This was so in 82% of his own series. Surgeons must agree that any operation that produced results of that order was a good operation, for none was known in any region of the body or for any condition that gave 100% of cures. The relationship between disk herniation and sciatica was now firmly established, but the history and clinical signs of both positive and negative groups were often identical. We needed to discover the differences between the two groups which should be there.

MEDICAL ASPECTS OF CHILD GUIDANCE

At a meeting of the Devon and Exeter Medico-Chirurgical Society at the Royal Devon and Exeter Hospital on April 15 Dr. HARDY S. GAUSSEN talked about some medical aspects of child guidance.

Dr. Gausсен said the child-guidance clinic was designed to deal with children in real difficulties. Studies of behaviour showed that children differed mentally from adults. The child's mind was still malleable and amenable to treatment where the adult's was rigid. The aim of treatment was to enable the child to achieve mental maturity. To bring this about it might be necessary to influence the environment, especially the parents, bearing in mind that when there was a conflict of ideas between parents and children the child was usually right. Common sense was not enough in child guidance. Team work was necessary, and the team consisted of the psychiatrist, the psychologist, and the social worker, other specialists such as the paediatrician and the special therapist being co-opted when necessary.

The approach to the problem was threefold: medical, educational, and social. Children were referred to the clinic by parents, schools, courts, and family doctors. Children who suffered from tantrums, screaming fits, sleep disorders, or who lied or were solitary, overactive, or aggressive, were problems to parents and teachers. Sick children—those with functional pain due to fears, with enuresis, with vomiting or anorexia, and with unexplained pyrexia—formed another group. A third group might be described as "magistrates' cases." Sometimes, but by no means always, these could be cured by a good beating. In Dr. Gausсен's opinion approved schools were not the complete answer; they got hold of the children too late in life. Those children in whom emotional difficulties caused diversion of energy and consequent backwardness at school were educational problems.

The whole team of a child-guidance clinic should examine each child. Physical disorders having been ruled out, the correct procedure was as follows; first, the social worker should visit the home to get as full a picture as possible of the child's background; secondly, the psychologist, usually a non-medical woman with a degree in psychology, should estimate the child's intelligence; lastly, the psychiatrist should get to know the child in a series of friendly talks, playing games perhaps, but asking no direct questions. The evidence should then be pooled and treatment planned. The combined investigation might reveal insecurity of various kinds—in relation to parents, to brothers or sisters, to being the odd man out at school, or to developmental conflicts. It might reveal educational difficulties due to a degree of intelligence superior or inferior to the rest of the class or to defects of vision or hearing or to left-handedness. It might reveal constitutional difficulties due to epilepsy or to spastic paralysis with concomitant mental defects, some of which cases inevitably ended in mental hospitals.

All these cases needed help from the child-guidance clinic. What could be done for them? Where possible, the cause must be found and treated. The parents must be guided. Social factors must be considered. It might be necessary to get the father a job, or get the school to change the child's class, or interview the schoolmaster and enlist his help in getting the child away from the mother's apron-strings. Methods of treatment might sometimes be applied with advantage to groups of children. In some cases institutional, and in others individual, treatment was the method of choice.

ALLERGIC CONDITIONS OF THE EYE

The second general meeting of the British Association of Allergists was held at Oxford on April 17. A discussion on allergic conditions of the eye was opened by Dr. VERA B. WALKER, who gave an account of her experiences during seven years' work. Dr. Walker presented some of her results obtained with specific desensitization, comparing them with those following non-specific desensitization with histamine-azo-globulin; where the specific allergen could not be determined desensitization with histamine provided an alternative line of treatment. Dr. Walker made special reference to three conditions—conjunctivitis, keratitis rosacea, and migraine. She emphasized the urgency of referring all cases of keratitis rosacea to the allergists for investigation, and indeed other patients with keratitis of unknown origin, especially those with a family history of acne, eczema, or urticaria.

Discussing the treatment of allergic migraine, Dr. Walker drew particular attention to the significance of a low systolic pressure. Although all cases of migraine were not of allergic origin, if a patient with true migraine had a low systolic pressure, then allergy should be suspected and treated appropriately.

The subject was then thrown open to discussion and Mr. FREDERICK RIDLEY, Mr. A. C. HOULTON, Mr. ANTHONY PALIN, and Dr. R. S. MACLATCHY contributed observations from the point of view of the ophthalmologist. Other speakers included Dr. A. W. SPENCE, Mr. DRUMMOND CURRIE, Dr. R. W. STEPHENSON, Dr. C. J. C. BRITTON, Dr. LIPMAN COHEN, Mr. VICTOR PURVIS, Dr. F. WRIGLEY, and Dr. D. HARKINS.

Preparations and Appliances

TRANSFUSION NEEDLE FOR INTRAVENOUS CANNULIZATION

Dr. J. H. WAELSCH, of the Central Laboratory, Bulovka Hospital, Prague VIII, writes: In carrying out transfusions, especially those repeated at short intervals, it is necessary to prevent damage to skin and veins which might arise from repeated insertions. The normal needles supplied with the various types of apparatus for drip transfusion allow direct piercing of the vein and skin, and have the disadvantage of leaving a sharp point in the vein, which not only endangers the vein by perforation but also irritates its walls and may cause the formation of small blood clots. Also, contact of the point of the needle with the walls of the vein may slow down or

entirely stop the transfusion. On the other hand, the introduction of a cannula damages the skin, even though the damage is slight. The place used is thus rendered unsuitable for transfusions at short intervals. This seems to be the case when using the method described by A. Clain (*Lancet*, 1947, 2, 830) who makes a short skin incision with a scalpel.

The type of transfusion instrument for intravenous cannulization described below, which we used for more than a year, makes it possible to pierce the skin as with the ordinary transfusion needle. It combines all the advantages of transfusion

by blunt cannula without necessitating the use of a scalpel, so that injections can again be made on the same spot within a very short time. It consists of the transfusion cannula, to which wings are attached, and an injection needle which is enclosed by the cannula. The illustration shows two types of the instruments, which are made in three sizes.

The injection needle fits tightly into the cannula whilst allowing of its being moved to and fro. The needle-tip lies immediately in front of the blunt tip of the cannula, so that no unevenness is felt by the patient when the skin is pierced. The mount of the needle and cannula can be attached to "Record" syringes. The mount of the needle is provided with a tooth to fit into a notch made in the base of the cannula to prevent independent rotation of needle and cannula. If no metal adapter is available the tubing of the intravenous apparatus can be attached simply by being pulled over the olive mount of the cannula. Wings, made of flexible metal with a roughened surface are fixed to the cannula.

Procedure.—Insert needle into cannula so that the tooth on the needle falls into the groove on the cannula, and attach syringe. Clean the skin of the patient and apply compression in the usual way. Pierce skin and insert the instrument into the vein. When it has been ascertained that the instrument is in the vein, release compression and withdraw the needle, leaving the cannula in the vein. It is essential that the instrument be inserted into the vein far enough, so that the cannula is still well in the vein when the needle has been withdrawn. The intravenous apparatus, which is set up in the usual way, is then attached to the mount of the cannula by an adapter or by the rubber tubing being pulled over the olive. The wings of the cannula, which can be shaped to the form of the limb, are then fixed with "elastoplast." When the transfusion is finished the cannula is withdrawn and the skin treated as after intravenous injections.

The needles were made for me by F. Špírk, instrument makers, Prague XVI, Hluboký 399, and can now be manufactured by Willen Bros. Limited, Surgeons' Instrument Makers, 44, New Cavendish Street, London, W.1.

In recognition of his doctor's "kindness, understanding, and devotion to duty" a Mr. J. L. Street, of Dewsbury, who died on March 31, has bequeathed his body to the doctor or his successor for medical research, reports the *Yorkshire Post*. The doctor concerned died last October himself and his successor has therefore accepted the bequest and given the body to Leeds Medical School.

Correspondence

Control of Regulations

SIR,—It appears that, while Mr. Bevan's recent promises have not satisfied many of the doctors, there is an even larger section of the profession which wishes to be rid of this controversy. The monster about to be born seems capable of creating great misery. Since we do not possess the power of superfecundation, all we can hope to do is to palliate the Minister's evil potentialities.

To the specialist, whose terms of service are to be determined by Regulation, a satisfactory check on Regulations would seem essential and sufficient. For the general practitioner there appears to be no public support for the retention of buying and selling of practices. The system of payment by capitation fee will exert an economic negative direction which will not be removed by annulment of the negative-direction order. Thus the only means of preserving his freedom is the same as for the specialist.

If there is still a vote for abstinence from the Health Service Act as it is to stand, a compromise proposal from the doctors would have considerable public support and be successful. In such circumstances I suggest a memorandum on the following lines: (1) The B.M.A. reaffirms its desire for a comprehensive health service. (2) If the Government will insert in the Amending Act a provision that the Regulations under the National Health Service Act, 1946, shall be subject to the provisions of Sect. 1 of the Rules Publications Act, 1893 (or a suitable modification thereof), and that the B.M.A. and Royal Colleges shall be considered as public bodies under this Act, then, notwithstanding the many and varied other objections to the Act, the B.M.A. will recommend the doctors to accept its provisions and work for its improvement. Better to have a solution on these lines than a fight in which all will suffer.—I am, etc.,

London, N.W. 11.

HAROLD E. THOMAS.

Comprehensive Service

SIR,—In common with many others I am at a complete loss to understand the policy of the B.M.A. in regard to the Health Act. Do they want the Act or do they not? Your leading article in the *Journal* of April 24 (p. 791) and Dr. Dain's letter (p. 805) seem to add to the confusion. Lord Horder's letter to the *Daily Telegraph* seemed almost to be an apology for Dr. Dain's speech, but at least it gave a clear view of the situation that will arise if the profession compromises on any of the B.M.A. four points.

I submit that even if all four points are conceded by the Minister we shall still be acting dishonestly to the public if we agree to participate in working the Act as from July 5. We know the facts about shortage of hospital beds, equipment, nurses, etc. We know that our middle-class patients will be particularly hit by the cost of the compulsory State insurance scheme and that the most of them will have to pay in addition for private ward or nursing-home in the absence of the promised free hospital bed. The present insured population will suffer greater hardship by this added competition for the available beds. We made no election promises nor did we distribute rose-tinted spectacles in 1945. Why should we now make ourselves the scapegoat of the politicians of all parties who blessed the Beveridge Plan?

I submit that the B.M.A. is wrong in reiterating that we all desire a comprehensive medical service, if by that they mean a service which is a necessary corollary of the Beveridge Plan and a service to which subscription by everyone is compulsory. The only comprehensive medical service to which I myself will subscribe is one which is open to everyone but to which everyone is free to subscribe or not. At least those who wish should have the right to contract out before we touch the Act.

It is not difficult to think that we can retain professional freedom, even if we take over four subsidiary and subsidiary points if we have sold the pass and let it be understood that with our medical features we will agree to work a

labour, plus compulsory State medical records of everyone, and you have the complete Nazi system in embryo thrust upon us. We cannot claim freedom for ourselves and at the same time become the agents of any Government, of any party or coalition, in binding a totalitarian system on the whole nation. To think such possible is a confession of a disordered mind. If we agree to work an all-in compulsory scheme like the Health Act, we shall sell out to Communism. I have voted "No," and mean to vote "No" as consistently as Molotov.

If the B.M.A. cannot act on the clear expression of the profession's opinion in the last plebiscite and leave the Minister to stew, to carry out his boast that he will work the Act with or without the doctors, and if in spite of this they must go running around to him for conversations, then the melancholy thought arises: Are there in high places in our Council some who really want this totalitarian Act to come into operation for personal reasons? If this be so, then for all time their honour will stand rooted in dishonour, for they will have manœuvred the free medical profession into becoming agents of tyranny.

Our ancestors fought and died for religious and civic freedom, and for myself I will never take part in thrusting the delusion of complete social security (whether supported in the name of Beveridge by Conservative or Socialist or Liberal Party) upon my fellow citizens. As students of biology we ought to know that we live in a competitive world where survival is only possible by individual effort. Our hospital system with all its human shortcomings is the visible expression of the Christian faith of our fathers. To hand them over to the State and to make them dependent on forced subscriptions is to admit that the compulsion of the Christian ethic no longer acts on our conscience.

It is a fact that nearly all thinking citizens are now looking to us as their last hope of freedom in our time. If we fail to stand fast then it will be for all time to our discredit as a profession. We blamed the Germans for not protesting at the risk of their lives against Nazism in its early days. The same choice is now before us as a profession, but with no comparable risks, if we refuse to become agents in binding our country with chains of tyranny.—I am, etc.,

Bournemouth.

DAVID HARDIE.

SIR,—You say in the *Journal* of April 17 (p. 737) that the profession is committed to a comprehensive medical service. This was a colossal and fundamental mistake and it is recognized as such now by the immense majority of the profession. Is it right that any profession or body of men should be tied to such a mistake made by their leaders? I am quite sure that if Mr. Aneurin Bevan found a mistake like that in his Act he would have an Amending Bill introduced into the House the next day. Let the Council take a plebiscite on the 100% policy and see what the result would be.—I am, etc.,

London, W.5.

J. B. MASON.

The Minister's Gesture

SIR,—While heartily welcoming the Minister's gesture and particularly the tone in which he spoke, I am afraid I see no great cause for rejoicing, nor for another plebiscite. After all, it is only a step—a small step, I feel—towards solving the problems confronting us. Apart from three rather minor concessions which are to be incorporated in the Act, the rest of our road seems paved only with good intentions couched in vague terms: "Not in prospect" (Question 3); "ought . . . to be ready to indicate its likely attitude" (Question 3); "appointed after consultation within" (Question 4); "will be asked to observe the wishes of" (Question 11a); "would be taken into account by" (Question 11d); etc. Not really very reassuring. I fear.

In the three "concessions" he is merely (1) incorporating in an amending Act an assurance he himself had already given (*Hansard*, Nov. 4, 1946, Vol. 428, C. 1125) ensuring that a full-time salaried service can only be instituted after a further Act of Parliament. (Is putting in writing what has already been promised verbally really a concession?) (2) Amending (if need be) the Act relating to partnership agreements, which was so ambiguous that grave injustices might have occurred. (Is amending an Act so worded that its meaning was ambiguous and liable to cause injustice really a concession?) (3) Juggling

A BIG STEP FORWARD IN BABY SKIN CARE

used after every
nipple change it helps
to reduce infant
skin irritations

BABY
LOTION

ANTISEPTIC

LEAVES A
DISCONTINUOUS FILM...

By using Johnson's Baby Lotion, particularly after nipple changes, you leave a soothing, discontinuous film over a baby's skin and the antiseptic in the Lotion protects against surface bacteria and so reduces the risk of urine rash and nipple rash. Johnson's Baby Lotion is a snow white lotion — an oil-in-water emulsion, homogenised under pressure to give extensive dispersion of the globules. It enables the pores to 'breathe' naturally and normally, allows perspiration to escape easily and so helps prevent irritation. Clinical and laboratory tests show that Baby Lotion is a big step forward in baby skin care.

The diagram summarizes the local and central actions of the drugs contained in 'Framol'. Clinical experience indicates that the combination gives more effective control than ephedrine and theophylline prescribed singly.

A noteworthy function of the 'Luminal' content is to allay anxiety: it keeps the patient physically and mentally at ease, inhibiting the sudden panic which sometimes precipitates an emergency call.

'FRANOL' (ephedrine + theophylline + 'Luminal') is supplied in packets of 20, 100, 500 tablets. The average adult dose is 1 tablet t.d.s., or 1-2 at the first warning of an attack.

with the strings attached to the unhappy basic salary. But the alary remains—a noxious thing. Obviously there must be something given for that £300 or the Treasury would veto a vast of public funds. Direction, or negative direction, seems indicated.

Freedom of speech and publication, though again assured verbally by the present Minister, are still not to be incorporated in the Act and so made binding on his successors. Ownership of goodwill, which would solve so many other problems (and make "concessions" Nos. 2 and 3 unnecessary) and for which a detailed, equitable, workable alternative has yet been put forward, has not yet been conceded. The powers of the "unofficial G.M.C." to prevent a qualified practitioner doing midwifery under N.H.S. remain. There is still no right of appeal to the courts, and the powers of the Minister remain such that he might well be renamed the Dictator of Health. We have stated what we consider essential or a satisfactory Health Service and have conceded all else. Now it seems to be suggested that as Mr. Bevan has made a gesture we should concede the rest.—I am, etc.,

Rusby,

R. PRESTON HENDRY.

Established and New Practitioners

SIR,—Mr. Bevan wishes to abolish the buying and selling of practices so that the young doctor shall start practice without financial difficulty. Many doctors agree, but it seems unfair if the institution of such an innovation, if proved a wise one, that practitioners already established and yet still treading the fires of financial stress should be penalized.

In the new Health Service a change for the better is to take place for the young doctor about to commence general practice. None is so conservative as to object to innovation to improve conditions for the next generation, but let it not be at the expense of those men in established practice who have in most cases already paid large sums of money in capital outlay; and subsequent sums to purchase additional shares and/or pay out a senior partner.

May I suggest that as at July 4, 1948, a line should be drawn between the old and the new, and that all doctors in established practice, whose names appear in the *Medical Register* and who have for so many years served the public faithfully and well, should be compensated adequately both for capital outlay and subsequent payments they have had to make while building a practice. More important still, that fair compensation should be paid to them, if they so desire, within a definite stated number of years (say, five)—those fortunate enough not to require their money immediately to be paid, as already suggested, at death or retirement.

The above suggestions are of little concern to the young man not yet embarked on G.P., nor to the doctor long enough established to have saved for retirement or old age. They do not apply to the main body representing general practice—doctors of ten years' standing or so—who have to meet the heaviest financial commitments of a busy practice and a young family. It is the vote of this group of practitioners which carries most weight in any plebiscite for or against a National Health Service.

Surely if these debatable points were concisely and quickly clarified, and the probability of realizing the capital value of a practice within a specified number of years was certain, there would be less apprehension for one's future financial stability, and with a mind composed each doctor would be better able to reconsider his decision for or against service in a national health scheme.—I am, etc.,

G. A. POWELL-TUCK.

Birmingham.

More Safeguards

SIR,—I am among the majority who desire to continue to refuse service under the N.H.S. until there is sufficient safeguard of the freedom of the profession. So far as general practitioners are concerned, for an eventual 100% Government service I am convinced that there are three essential safeguards of our security which have not to my knowledge so far featured in such negotiations as have taken place. They are:

(1) Complete removal of the power of dismissal from the Service from the hands of the Minister and of any committee

under his jurisdiction. Dismissal should be in the hands of the General Medical Council, as it is equivalent to removal from the *Register*, and should be allowable on ethical grounds only—i.e., for neglect of patients and not for neglect of regulations. Breaches of important regulations could be dealt with, if considered necessary, by other means such as fines.

(2) Inclusion in the Act of the scale of remuneration in general terms—e.g., that it shall be in accordance with the recommendations of the Spens Committee. Details of its interpretation may then be subject to negotiation between the Minister and the profession.

(3) Inclusion in the Act of the recognition of the British Medical Association as the authorized negotiating body for general practitioners. If this is not included the Government may at any time after our acceptance of service rule that collective action by the B.M.A. is illegal, since it is not a trade union.

Whatever the outcome of negotiations about retention of goodwill, negative direction, etc., I believe these three practical points to be fundamental to our security after the Service has been joined.—I am, etc.,

Hove, Sussex.

E. N. G. GORMAN.

Alternative Service

SIR,—I believe that this latest plebiscite will show a smaller all-round vote and a smaller number of outright rejections of the Service because many of us feel that the "Molotov" attitude is not enough, that the B.M.A. should be telling the Government and the public, especially the latter, what we will do rather than merely what we will not. If my forecast is wrong there is no more to be said; if it is correct there is still time to modify our method of counter-attack.

While those of us who are in medicine know well enough that the new Service will make no difference to the health of the people, we must recognize that the great mass of people wish to pay for medical treatment on a contract basis. This is the essence of the new Act and ought, I believe, to be accepted by the doctors. All the points to which we have made strong objection are not essential and may justifiably be rejected.

I suggest that the profession should make a declaration to the public and to the Government along these lines: (1) We agree to run a 100% service to be paid for on a capitation basis at a rate in conformity with the Spens Committee report (Patients preferring private attendance could still obtain it and would not necessarily lose sick pay, since private certificates would be accepted.) (2) The question of the buying and selling of goodwill, direction, etc., to be postponed for five years. If after that time it can be shown that the Service is not working effectively for lack of these elements, the Government can approach the profession afresh in respect of them.

I submit that this procedure would have the following advantages: (a) It would demonstrate to the public that we are not trying simply to prevent the introduction of the new Service for our own ends but are prepared to serve them adequately. (b) It would, I believe, be endorsed by a greater number of general practitioners than rejected the Service in the last plebiscite. I can say nothing as to the consultants, since I have no more idea than they as to what they are being offered. (c) Five years' participation in a national service would bring the solidarity of the profession (so much a product of this controversy) to the same level of effectiveness as the National Health Insurance Service has achieved; and less than two years ago we had a useful demonstration of what this means in negotiations with the Government.—I am, etc.,

Northwich, Cheshire.

J. BOYD FULTON.

Postpone Service

SIR,—In the beginning Mr. Bevan was briefed to take the proposed new Health Service and work it according to certain principles. In order to achieve this object he devised his battle orders in two distinct phases. The attack in phase I, in which the National Health Service Act passed into the Statute Book, was directed at the general public and Members of Parliament. Doctors' representatives were first ignored and then abused. Soon after the Bill became law phase II was put into operation and is now nearing its height. Its objective is to lure the

profession into the trap. Notice how the technique has changed. The Minister is now conciliatory and makes "considerable" concessions to this reactionary profession. There are ominous signs of weakening in the Council of the B.M.A., as reflected in the wording and tone of the last leading article (April 17, p. 757).

We have stated publicly that we will adhere to our four "freelancers," which we regard as essential for the protection of our patients and ourselves. Nothing has changed since that decision to alter the material position in any way. Mr. Bevan has done exactly as Dr. Dain forecast weeks ago. He has given way on one small point in order to force a breach in our defences. Our answer should be to close that breach with a decisive "No" to the plebiscite question.

In my view the Act's implementation should be postponed, even if there was agreement on the main clauses, until the detailed terms of service such as hours of work, secretarial assistance, and holidays have been decided. It seems to me incredible that we are being asked to sign on for a lifetime's job with no possibility of an alternative, and are told that the conditions of work will be settled "later on."

As has been stressed so often, our strength is in unity. By sticking together we can postpone this change for the worse in the medical services of this country and so easily make it a change for the better. The National Health Service Act contains so much that is good that it is a pity to pluck the fruit until it is ripe, and until the maggot has been removed from within.—I am, etc.,

ROSE M. DEVEN

KENNETH INMAN.

The Plebiscite

SIR,—I wish to record my protest against the hurried manner in which the recent plebiscite has been conducted. It seems to me entirely wrong that any medical man should be expected to make what is, or ought to be, a major decision in his life without opportunity for due consideration and discussion with his colleagues.—I am, etc.,

DOUGLAS ROBERTSON.

Position of Assistants

SIR, Dr. John Gemmell's letter (April 24, p. 810) rightly stresses the unsatisfactory position of present-day assistants, both now and in the future Health Service. Nothing has emanated either from the B.M.A. Council or from the Minister to guide and encourage them. Indeed, it would appear that in the future, as in the past, their role will be the same—a source of cheap labour, liable to a month's notice at any time and *pointedly* directed from the area by restrictive covenants in their agreements, although, as Dr. Gemmell says, they may have built up "a certain goodwill by their own merit."

The Act at present provides that assistants will not be eligible for automatic inclusion in the list of doctors participating as principals in the new Service. An assistant, however, will be able to continue to assist any doctor permitted to have an assistant, or to secure admission to the list as a principal if the Medical Practices Committee consents. This of course means if his employer consents; for the Committee will naturally consult the principal regarding his assistant's application. The assistant therefore remains at the mercy of his principal. He can be given notice at any time without reason, and yet he may be as good a doctor as his principal, as well beloved by his patients, and as keen as ever on working in the area which he chose when he took on the job.

Dr. Dain, the day after the Bill received the Royal Assent, informed me that the Minister was to be impressed that restrictive covenants in partnership agreements must continue. The Minister has agreed to this, apparently, for there is nothing in the Act as it stands which precludes such clauses from operating after 1948. It seems to me that he has in my opinion given principals a protection which they are not entitled in law (it is one of the *conventional* conditions of the B.M.A., although we hear little of it) to demand.

See the statement of the case *Roth and Wilson v. Jones* before the High Court in 1947, and later before the Court of Appeal in 1947, p. 760. It was established that a principal is not protected in law from competition by a previous assistant, and that the knowledge which the assistant has of the practice may be used by the patients of the practice may

adversely affect the selling value of that practice. The Health Act provides full compensation for the selling value of the practice of a principal entering the Service. Why, then, should the principal be still further protected from competition by a previous assistant? There is no protection in law against free competition, and the B.M.A. indeed insists that it is essential to ensure good work.

If the present status of the assistant is allowed to continue it means that his income will be restricted to the present rate of pay while the principal reaps the financial advantage of an extra 2,400 capitalisation fees. I would therefore support Dr. Gemmell (and the other writers whose letters have appeared at infrequent intervals without stimulating any official reply) in asking that the position of present-day assistants be classified. There are many with first-rate experience who, because of their war service and the financial loss they have in consequence suffered, find themselves forced to take assistantships in order to provide for their families. Some of them, principals before the war, lost their practices and in some cases their property too. They cannot afford to buy practices, houses, and equipment at to-day's prices. They are, I believe, entitled to more consideration from the B.M.A. Council and from the Minister than they have so far received. They are also entitled to a measure of representation.

There is no reason, if B.M.A. principles are sincere and apply to all members of the profession, why any assistant in the future Service should be prevented from practising as a principal in the area in which he has served as an assistant.—I am, etc.,

Okehampton, Devon

C. G. JONES.

Bewildered Practitioners

SIR,—On demobilization after the recent major conflict I was vaguely surprised that the B.M.A. took so little notice of the "returning doctor." However, I comforted myself with the thought that the entire organization was probably concerned with working out operational orders for "Operation Bevan." Since that day I have listened to a vast quantity of irrelevant ideas propounded by elderly practitioners whose lack of understanding of the problems of the young ex-Service doctor is only surpassed by that of the Royal Colleges when it comes to general practice.

While we talk and negotiate and vote the sands are running out, and on July 5 a herd of bewildered practitioners will join the Service because nobody has told them what to do if they stay out. So let us have some clear-cut directives from the trustees of the Independence Fund, and let us have them at once, so that local schemes can be worked out ready for the appointed day.—I am, etc.,

St. Neots, Hunts.

IAN H. BARTLEY.

N.H.S. Capitation Fee

SIR,—It seems to have escaped general notice that the capitation fee of 18s. which we shall receive under the new Health Act (it will be less in most cases after the first charges have been deducted from the pool of £41,000,000) falls short of the figure, translated into 1948 values, recommended by the Spens Committee Report by more than 5s. per head. The Government promised to implement the Spens Committee recommendations. How some of us appear to be fooled about this, as well as about the infinitely more important issues of our professional freedom and fundamental civil rights, is beyond comprehension.—I am, etc.,

Salisbury.

PAUL HARRIS.

Statement to Patients

SIR,—At a meeting of local doctors the following statement, for display in waiting-rooms on and after April 5, 1948, was signed by 24 out of 25 doctors engaged in general practice in the area.

We, the undersigned medical practitioners, practising in the Ilarefield, Ickenham, Hillingdon, Uxbridge, Yiewsley, and West Drayton Areas, while welcoming a Health Service suitable for the whole community, consider that the National Health Service Act of 1946-7 as at present enacted would be detrimental to the welfare of our patients and the proper practice of medicine. For these reasons WE HEREBY GIVE NOTICE to our patients that in accordance with our rights under the said Act, we will not enter into any statutory contracts of service as provided for in the said Act IN THEIR PRESENT FORM.

—I am, etc.,

R. A. G. HAMILTON.
Local Hon. Secretary

Uxbridge, Middlesex.

Freedom not to Treat

SIR.—During the past months a great deal has been said about the undesirability of central control of treatment, but I wonder if anyone can help me to solve this type of problem. Take a recent experience of mine: I am consulted about a young woman whom I find to be a fairly florid schizophrenic unsuitable for admission to my general hospital. The relevant county mental hospital does no insulin treatment on the female side. The neighbouring county mental hospital does but cannot undertake treatment of "non-domiciled" persons. The nearest city mental hospital can do so but does not do insulin treatment on the female side owing to shortage of staff—and so on over an area of several thousand square miles. An application to an L.C.C. mental hospital for assistance draws advice to get her admitted locally or wait until July 5.

For about half of the modern "psychopathological" period insulin has been recognized as the weapon of choice for this illness, and to-day, 13 years after 1935, I cannot get this girl treated even as an act of grace.—I am, etc.,

Norwich.

R. LOUIS ROSE.

Acute Intussusception in Childhood

SIR.—In their interesting discussion of the diagnosis of intussusception in infancy (April 24 p. 776) Drs. Brenda Morrison and Donald Court make no mention of a finding which seems to me perhaps the most helpful and significant of all. On making a rectal examination, when the finger is withdrawn, in intussusception and in intussusception alone there is absolutely no faecal odour upon the finger-stall, even when it is smeared with mucus and blood. In all enteric infections, on the other hand, the odour is always strongly faecal.

One other point seems to me important, because it is apt to convey a deceptive reassurance. For long, in the intervals between the pains, the baby commonly falls asleep and may present all the appearance of normal, peaceful health, so that for anyone not familiar with the condition it is difficult to believe that the danger is so urgent.—I am, etc.,

London W1

HECTOR CHARLES CAMERON.

Iron-deficiency Anaemia in Pregnancy

SIR.—I was interested to read the article by Prof. L. S. P. Davidson and Dr. R. H. Girdwood (April 17, p. 733) on the subject of the treatment of refractory iron-deficiency anaemias with intravenous iron. Although engaged wholly in general practice, with its limited but frequently underestimated opportunities for clinical investigation compared with the facilities offered in hospital, I have for some time taken considerable interest in the treatment of iron-deficiency anaemia in pregnancy.

From about the sixth month of pregnancy onwards the foetal demands increase rapidly, and when the physiological anaemia of pregnancy has been excluded and a true iron deficiency exists, oral iron therapy has been found to have several disadvantages:

1. An appreciable number of cases show intolerance to iron administered by the oral route, and symptoms of alimentary irritation such as flatulence, nausea, anorexia, and diarrhoea make adequate dosage impossible.
2. In those cases in which symptoms of intolerance are not so prominent, unsatisfactory increase in the haemoglobin level is frequently observed. This is probably associated with the hypochlorhydria or achlorhydria which is a more common finding at this stage of pregnancy.
3. It is most desirable to ensure maximal haemoglobin levels and adequate iron storage at the time of parturition, but time may be too short to achieve this by oral therapy.

I feel, therefore, that any form of therapy would be most valuable which would tend to ensure maximal haematological response, and which would not be influenced by those factors already mentioned which interfere with the absorption of iron from the gut and with its subsequent utilization in haemoglobin synthesis.

When Nissim's paper appeared, on the use of intravenous iron in hypochromic anaemia (*Lancet*, 1947, 2, 49), I felt that a safe and effective preparation of this type might be of definite assistance in my own investigations. It appeared, however, that the method of preparing solutions of saccharated oxide of iron was not at that time sufficiently reliable to ensure the production of similar batches

of material, at all times free from toxicity, with standard therapeutic effectiveness after efficient sterilization. This difficulty has been stressed in Prof. Davidson's recent paper (April 17, p. 733), but some months ago I was able to obtain a solution of saccharated oxide of iron (containing 2% of iron) which is evidently prepared by a process fulfilling the requirements mentioned.

I have carried out investigations with this preparation on a series of cases, both at different stages of pregnancy and during the puerperium. The majority of the cases were ambulatory, and no difficulties have occurred during treatment. During this investigation considerably more than one hundred 5-ml. and 10-ml. injections of this preparation have already been administered in a period of over three months, and I agree with the statement made by Slack and Wilkinson (April 17, p. 733) that the injections present no special difficulties after the simple technique has been acquired, and no elaborate precautions have to be taken other than gradual dosage increase and slow administration.

This investigation is proceeding and detailed clinical results will be described later, but I can state that my preliminary observations show a dramatic response to this treatment when a true iron deficiency exists. The absence of the symptoms of intolerance associated with oral iron administration already mentioned and a satisfactory rise in the haemoglobin percentage enhance the feeling of well-being and contribute substantially to the patient's confidence and co-operation.

I have found that intravenous iron therapy administered before parturition ensures adequate iron reserves in the body in addition to correcting the anaemia. As a result, satisfactory haemoglobin levels have been effectively maintained after parturition without further need for iron by any route.—I am, etc.,

Kiddermore Staffs

D. G. FRENCH

Iron in Anaemia

SIR.—With reference to the question and answer on iron in anaemia (March 27, p. 625), it is suggested that ferrous iron is rapidly converted to the ferric state in the patient with achlorhydria but that there is little clinical evidence in support of this. I have observed anaemia to follow gastrectomy and have also noted that giving iron by the mouth is sometimes ineffective as a cure. Two obstinate cases were cured by giving to one extra milk and intramuscular calcium, and to the other intramuscular calcium alone.

The latter is a woman of 50 who was seen a year after gastrectomy with Hb 58%, brittle finger-nails, falling thin hair. Neither iron nor calcium by the mouth was tolerated, so intramuscular calcium with vitamin D was given on alternate days for six weeks. The Hb rose to 92%, the hair and nails soon began to recover, and she regained her lost energy. This sequence of events has been repeated twice.

The question arises as to whether a lack of calcium can cause an inability to absorb iron, or whether calcium can under some circumstances "save" iron, or whether the improvement in nutrition caused by the calcium and vitamin D was responsible for the better absorption of iron. It has been noted that general improvement in diet improves the Hb in the circulatory blood, and that is perhaps why Hb estimations in expectant mothers in this country to-day are higher than before the war, for their diets to-day contain certainly no more iron but equally certainly more milk.—I am, etc.,

Leeds.

R. A. MURRAY SCOTT.

Lupus and Cod-liver Oil

SIR.—Dr. G. B. Dowling *et al.* (March 6, p. 430), quoting a recent American article, state that Emery in 1848 first described the treatment of lupus with massive doses of cod-liver oil. This is incorrect. Devergie's original paper (*J. Méd. Chir. prat.*, 1848, 19, 411) on this subject appeared in May, that of Emery in September (*Rev. méd.-chir. Paris*, September, 1848). Devergie states that he had used cod-liver oil—the most fishy "Thuille brune" variety—as well as other treatments for eight years, and that "aujourd'hui je n'hésite pas à déclarer que c'est de tous le plus efficace: je vais plus loin, et j'avance qu'administré suel il guérit. Cette assertion est tellement vraie, qu'à partir du moment où ce moyen a été mis en usage par quelques-unes de

542 MAY 8, 1948

pas malades, les autres m'ont successivement prié de le leur faire prendre." The dose was "une cuillerée à bouche" night and morning, which was increased every two or three days by another tablespoonful, until about three were being taken at one time. When once this dose was reached most patients ceased to dislike the oil, so that it could be rapidly increased to the desired maximum of 12 to 14 tablespoonfuls daily. Treatment had to be continued for three to six months or even longer. The appetite of the patients decreased but their weight and general well-being increased.

Emery's original paper is not listed as being available in any library. The American reference to it is really a reference to an abstract—an abstract which was apparently inaccurate in 1848 (*Bull. con. Thé. Paris*, 1848, 45, 466) and which in its turn has been inaccurately summarized in 1947 (*J. Lancet*, April, 1947, p. 152). Indeed it appears to be impossible to know now what Emery really wrote, let alone what he really did; but it seems incredible that his patients drank 1,000 g. (nearly 2 pints) of cod-liver oil daily, while the 12 to 14 tablespoons (about one-third of a pint) of Devergie are at least possible. Can it be that Emery was the result of a juvenile frolic of Karl Friedrich Hieronymus, Baron von Münchhausen (1720-1797)?—I am, etc.,

1-15-48, W.I.

FRANKLIN BICKNELL.

Papworth Village Settlement

SIR.—When the Disabled Persons (Employment) Bill became law it was apparent to workers in the tuberculosis field that the facilities for training and employment provided therein, while suitable for the ordinary disabled person, were hardly possible of application to the man and woman disabled by tuberculosis. For some time past negotiations have been going on between Papworth Village Settlement and the Ministry of Labour to provide some scheme for training which would be of assistance to tuberculous sufferers. The Ministry of Labour has now agreed to recognize as vocational trainees all trainees (other than Ministry of Pensions cases) at Papworth who are able to work for a minimum of three hours a day. This recognition will extend to those who have completed their sanatorium treatment elsewhere as well as to patients who have received their sanatorium treatment at Papworth.

The following terms have been agreed:

- (1) Training allowances will be paid to all recognized trainees on the basis set out below; sickness benefit will not be payable.
- (2) The Ministry will pay hostel charges in respect of each recognized trainee at the rate of 28s. per week for men and 22s. 9d. per week for women.
- (3) No training grants will be paid to the Settlement by the Ministry.
- (4) The period during which the Ministry will pay training allowances will depend on the trainee's progress. It is understood that the training period is likely to be well under two years. In no cases will allowances be paid for more than three years.
- (5) When a trainee has finished training he will be considered for admission to the Settlement at the trade union rate.
- (6) Quarterly reports will be rendered to the Ministry of Labour, and if it appears that the trainee is unduly prolonging the period of training or otherwise proves that he or she is unlikely to benefit from further training, the Settlement will advise the Ministry of Labour. Reports will also be rendered if so desired to the Local Authority responsible for treatment.

TABLE I.—Persons Aged 20 and Over

Pay	Amount per Week	
	Men	Women
A	36s.	28s.
B	42s.	31s.
C	48s.	35s.
D	50s.	43s.

a man or woman with an adult dependant other than a wife and one or more dependent children.

TABLE II.—Persons under 20 Years of Age

Age	Amount per Week	
	Young Men	Young Women
19	26s. 6d.	24s.
18	23s. 6d.	23s.
17	22s.	21s.
16	22s.	21s.

The allowances are payable without regard to any payments received from the Service departments during paid furlough or to any disability pension or similar allowance (excepting those cases already excluded from the scheme—i.e., Ministry of Pensions treatment allowance cases).

Persons who leave home for training will receive, in addition to the appropriate rate of allowances, full board and lodging free of charge. A person in training away from his home area who continues to maintain his former home may receive additionally an allowance of 24s. 6d. a week.

Married men under 20 years of age, and in certain circumstances unmarried men aged 19 and women aged 19 who have dependants, receive allowances at rate (B) or (C) or (D) above, as appropriate.

Other persons under 20 years of age who have dependants receive 10s. for an adult dependant and 5s. for a dependent child under 16 in addition to the allowances set out in Table II.

During periods of sickness of a week or more training allowances will not be paid. Sickness benefit and training allowances will not be paid concurrently.

This scheme will now enable local authorities to send selected cases to Papworth at less cost than hitherto, as part of the cost of maintenance will be borne by the Ministry of Labour (see (2) above). The decision as to suitability for admission to Papworth and the scheme will rest entirely with the medical staff at Papworth, who will require full clinical details and x-ray films in each case from the tuberculosis officer.

Both the Committee of Management of Papworth Village Settlement and the Ministry of Labour feel that this is a considerable step forward in the rehabilitation of the tuberculous, and anticipate its extension in the future. To this end the Ministry has undertaken to provide half the cost of two hostels of 50 beds each for men and women at Papworth.—I am, etc.,

Papworth Hall, Cambridge.

RICHARD R. TRAIL,
Medical Director.

Thiosulphate as an Aid to Chemotherapy

SIR.—A recent report by Lorant¹ on the subject of the non-specific chemotherapy of malaria by thiosulphate has given us a great satisfaction, for during the war we carried out experiments from a similar view-point and obtained similar results.² We had previously confirmed the fact that thiosulphate, in spite of its being a single inorganic substance of a simple chemical constitution, acts in various cases (lewisite, mustard gas, cyanide, and carbon monoxide poisoning) like a "universal detoxifier" (Kabelik³), and this may probably be ascribed to the following factors: (1) Thiosulphate as the neutral salt of thiosulphuric acid behaves like an inorganic glutathione, combining with certain toxic agents and rendering them practically non-toxic. (2) Being oxidatively converted to sulphuric acid, thiosulphate supplies an abundant exogenous source of ethereal sulphates. (3) Thiosulphate intensifies the biological defence reactions by activating the reticulo-endothelial system.

In addition to the detoxifying actions as above mentioned, thiosulphate possesses an activating effect on certain chemotherapeutic agents, particularly neoarsphenamine in syphilis and "optochin" in serpigulous ulcer of the cornea. In both cases thiosulphate not merely elevates the tolerance of the organism for those agents, but also seems to increase more or less markedly their bactericidal effect.

Suggested by these inferences, we undertook a few experiments on birds concerning the effect of combination of thiosulphate with quinine in comparison to the routine treatment with quinine alone. Canaries were inoculated with *P. praecox*, and three days after this they were divided into three random groups and subjected to the following procedures:

1. Quinine and thiosulphate group. The birds were injected daily with 0.2 ml. of 2% calcium thiosulphate solution (corresponding to the confirmed optimal dose of about 0.2 g. per kg.

A and B apply to persons without dependants. Rate B applies to persons with one or more dependent children under 16 but with no other dependants. Rate C applies to a married man with wife or a married woman with husband. Rate D applies to a married man with wife and children or a married woman with husband and children under 16, or in certain circumstances

body weight) and one hour later with 0.2 ml. of 0.5% quinine hydrochloride solution.

2. Quinine group. The birds were injected daily with 0.2 ml. of physiological saline solution and one hour later with 0.2 ml. of 0.5% quinine hydrochloride.

In both groups the injections were given intramuscularly and repeated for four consecutive days.

3. Untreated control group.

From the fourth day of inoculation parasites were examined almost daily microscopically by Giemsa's method. The intensity of their development was estimated by counting them in a given number of fields.

On an average, the degree of development of parasites on the 12th day in the quinine-thiosulphate group corresponded approximately to that of the 9th day of the quinine group, and it can be said that in the experimental conditions thiosulphate brought about an inhibition equivalent to about three days. This result may be attributable, apart from the three factors already mentioned, to some degenerative changes in the protoplasmic constitution of the microbes caused by direct action of thiosulphate upon it—Kritschewski's thiosulphate phenomenon.⁴ Further, it can be expected that quinine may be replaced by mepacrin, or any other new antimalarial agent.

Systematic clinical examinations of the combined treatment suggested above have not yet been undertaken in Japan, but experience has shown us that the most adequate route of administration of thiosulphate is the intravenous injection.

In conclusion we hope that the field of the combined application of thiosulphate as a common, non-toxic activator of chemotherapy need not be restricted to malaria, but will find a widespread extension irrespective of the nature of the chemotherapeutic agent—e.g., sulphaniilamide etc. Out of three cases of kala-azar, resistant to antimony preparations, successful results were obtained promptly through the combined thiosulphate treatment.—We are, etc.

Poliomyelitis and Lymphocytic Meningitis

SIR.—When presenting his neurological experiences in the Middle East and India at the Royal Society of Medicine Dr. Douglas McAlpine¹ in his discussion on acute benign lymphocytic meningitis stated that "neutralization tests in some of these proved that the majority were not due to the virus of acute choreomeningitis." He then went on to say that "in 1941 abortive cases of poliomyelitis were reported by Major Caughey, N.Z.A.M.C., thus making the sorting of these cases of lymphocytic meningitis more difficult."

The facts are as follows. Between November, 1940, and July, 1941, an epidemic of poliomyelitis occurred among New Zealand troops in the Middle East. This has been recorded in the *Medical Journal of Australia* by myself and Dr. Porteous.² Out of 30 cases 21 were the pre-paralytic type, with changes in the spinal fluid but no paresis. At the time Dr. McAlpine stated in a report that these cases were not cases of poliomyelitis, although they had come from the same division, the same units, and occurred at the same time as the 19 paralytic cases.

In the *Journal of Dec. 27, 1947* (p. 1019), in a paper on acute poliomyelitis, Dr. McAlpine and others again make reference to acute benign lymphocytic meningitis when discussing the differential diagnosis. When speaking of acute choreomeningitis they state that they "are not convinced that up to the present this condition has been at all common in this country [U.K.], although it should be added that many cases were seen in Service personnel in the Middle East during the late war." There is a marked discrepancy between this latter statement and that Dr. McAlpine made in 1945 at the Royal Society of Medicine. As far as I was aware on no occasion was it established by neutralization tests that acute choreomeningitis occurred in the Middle East among Service personnel, but I am open to correction on this point.

Finally, Dr. McAlpine and others state in the summing-up that in England "the virus of acute poliomyelitis should now be regarded as the usual cause of a benign type of lymphocytic meningitis." Hence they will allow of the diagnosis of pre-paralytic cases of poliomyelitis in the United Kingdom, but

Dr. McAlpine persists in his denial of such cases in the epidemic of poliomyelitis in the Middle East. He cannot have it both ways.

I am entirely in agreement that during an epidemic of poliomyelitis by far the most likely cause of cases of acute lymphocytic meningitis is poliomyelitis, but the exact diagnosis can only be made by serological tests and animal tests. Until such are more readily available, during an epidemic of poliomyelitis cases of acute lymphocytic meningitis must be regarded as being due to poliomyelitis.—I am, etc.

Fear and Pain in Childbirth

SIR.—Dr. J. Donaldson Craig (April 10, p. 769) makes the point that the pain of labour may be modified, if not entirely eliminated, "by the degree of confidence reposed in medical attendants." A very great deal has been written about the physical pain of labour, but little attention has been paid to what Head describes as "the diminution of general resistance to painful impressions" by "debilitating psychological states, such as anxiety or emotional shock." If certain obstetricians are able to conduct relatively painless labour without anaesthesia, surely it is by the elimination of fear. Is it not time that we devoted more attention to this aspect of the matter?

It is difficult for anyone long familiar with anatomy and accustomed to the facts relating to the physiology of labour to enter imaginatively into the state of mental ignorance in which many women are still allowed to approach their first confinement. If equipped with an assortment of half-digested facts about her body acquired from popular medical literature and first-hand classes, the young primigravida waits in the chair, queue next to a formidable mother of five. She may be encouraged by the resulting confidence, as Dr. H. Teitelbaum (Feb. 14, p. 316) optimistically suggests, but unfortunately we know that she is more likely to gather a terrifying impression of "instruments" and "violence." Her own idea of the birth canal must inevitably be that it is small, since her experience of it is limited to coitus and the insertion of vaginal tampons. How can so small an aperture allow the escape of a baby without some gnawing destructive process? As a rule true fear and its associated images are suppressed, and are only shown by an inability to relax during examinations. A simple but graphic explanation about the size of the bony pelvis and the softening processes in the connective tissue vagina will give immediate and lasting relief. If our clinics are too crowded to allow time to probe for these fears, information should be made available to mothers through simple lectures or discussion groups.

The primigravida frequently comes to her confinement in a state of apprehension. In many maternity departments she is admitted in a glare of lights on to a high white bed with a good view of the instrument cupboard. A sterilizer may be boiling up the forceps, presently to be lifted out in front of her, for Mrs. Jones moaning audibly next door. In this year of grace there are still communal labour wards, and she may find herself in the company of one or more pain-weary women more advanced in labour than herself. Confidences are soon exchanged, and they are not such as to reassure. Someone in a white coat appears and examines her. Notes are written and drugs ordered, but remarks to the patient are confined to kindly meaningless phrases which give nothing away and therefore do not allay her fears.

Kindness, though it abounds, is unfortunately not enough. We are all straining to be kind, but custom tends to dull our perception of the inner significance of birth as it is experienced by the mother. It is easy to forget the fear of the unknown and the sense of mystery and miracle which preoccupy her mind while we are debating some obstetric problem. We need to be more sensitively aware of the emotional side of the patient's experience if we are to avoid all these petty unconscious cruelties to which we subject her by our failure of imagination. By eliminating these we may do much to remove the part of pain which is made unendurable by fear, and the fear which may in itself be worse than pain.—I am, etc.

London, W.11.

Pain in Phantom Limbs

SIR.—In discussing the treatment of painful phantom limbs "Any Questions?" April 24, p. 817) you rightly stress the disappointing results from such measures as excision of neuro-ma, neurectomy, posterior radicotomy, and stump remodeling operations. You conclude that "the management of these cases is distressingly difficult," but make no suggestion regarding treatment except to advise the patient to persist in the wearing of the prosthesis.

While it is quite true that many heroic surgical measures, including even chordotomy, tend to be ineffective in this condition, it should surely be noted that excellent results are often obtained following 1% procaine injection of the sympathetic nerve supply to the affected limbs,^{1,2,3} or even from local injection of nerve trunks and scar tissue. The benefit so produced frequently passes off within a short time, but the procedure can be repeated indefinitely and the periods of remission tend to become longer, so that complete cure may result from three or four injections.

It is commonly held that, while phantom sensations are of almost universal occurrence after amputation, actual pain is comparatively rare. In a small series which I have recently studied closely⁴ it was found that bouts of pain, sometimes extremely severe, commonly occurred during the first six months after operation. The intensity and frequency of these painful episodes generally diminished with the passage of time, so that by the end of a year or so symptoms were not serious enough to demand treatment other than explanation and reassurance. With only one exception none of these patients has sought advice for symptoms which, although distressing, appeared to them to be so unreal and fantastic as to suggest that they were the product of disordered imagination. One very intelligent subject remarked, "I did not report sick, because I did not expect a doctor to treat a ghost."

It may therefore be that phantom pain is very much more common than is generally believed, and that we are called upon to deal with only that minority of patients in whom spontaneous remission does not occur and who are accordingly driven to seek advice. Amputation inevitably implies nerve injury, and it is therefore reasonable to suppose that in a certain proportion of cases a condition may develop which is directly analogous to the causalgia which sometimes results from other nerve injuries.⁵ Pain so caused is localized in the sensorium in terms of the established "body image," and so is interpreted as being felt in the phantom.⁶

The persistent symptoms experienced by such patients are very real indeed, despite the frequent paucity of demonstrable abnormality in the stump, and they may lead to complete breakdown of physical health and emotional stability, as in one unfortunate case in my experience. Therefore, although the difficulties and disappointments in treatment are realized, it is suggested that a largely nihilistic therapeutic approach is unjustified when simple methods of proven efficacy are available.—I am, etc.,

J. DONALDSON CRAIG.

Treatment of Pruritus Ani

SIR.—The variety of methods of treatment and the frequent therapeutic failures in pruritus ani are probably due to a lack of recognition of the fundamental cause of the complaint. This cause, however, is always the same. It is the exposure of the perianal skin to particles of faecal matter. The perianal skin normally possesses a specific resistance against the irritation caused by adhering particles of faeces following defaecation. In the elderly, however, this resistance breaks down. This breakdown is more marked in middle and old age, more seldom in younger age groups, and practically never in the young and adolescent. The breakdown has set up, therefore, develops a vicious circle. The breakdown leads to scratching and excoriation, the faecal matter penetrates into the crevices of the damaged skin and

aggravate the irritation, and so it goes on until a kind of perianal eczema develops.

The rational treatment therefore has to be both palliative and causative. The most suitable palliative treatment proved to be radiotherapy. Three doses of 100 to 150 r at weekly intervals of a radiation produced at 90 to 100 kV and filtered through 1 mm. of aluminium are usually sufficient to clear up the eczematous condition. In some cases a fourth treatment after one more week may be required.

The treatment is best given with the patient in the knee-elbow position and the buttocks pulled apart so as to expose the anal region. The width of the field depends on the extent of the skin involved. When large fields are used it is necessary in male patients to protect the testicles by a sheet of lead or lead-rubber.

The causative treatment, which should be begun at once, consists in washing with soap and water the anal region after every defaecation. Not only must the surrounding skin be washed, but the lining of the anus must also be cleaned by pushing the soaped finger inside it. All traces of soap must be rinsed away with water, the skin dried, and a dab of calamine lotion applied to the area. This treatment must be rigorously carried out indefinitely if recurrences are to be prevented.

This treatment has been uniformly successful in over 50 cases of pruritus ani. The few recurrences observed occurred only where the patient omitted to carry out the washing, and a final cure was achieved when regular washing was resumed. Mild cases may yield to washing alone without x-ray treatment. Occasional irritation may be relieved by one or two applications of "nestosyl" ointment.—I am, etc.,

St. Peter Port, Guernsey.

ALEXANDER ORLEY.

D.D.T.

SIR.—In the leading article entitled "D.D.T. in Use" (April 3, p. 648) you list the drawbacks of this insecticide and discuss briefly the ways in which these may be overcome. One or two points were made, however, which, we venture to suggest, require further consideration.

It was stated that D.D.T. is apparently lethal to all insects and acarines. That is, in our opinion, a somewhat arbitrary statement, as D.D.T. is certainly not lethal to all acarines—the glasshouse red spider being a case in point—nor is it toxic to all insects. Much work will have to be done before anything like complete information is available as to the relative toxicity of D.D.T. to arthropods in general, but with our present knowledge and methods of formulation your statement is incorrect.

The several problems of irritancy, the lag in acquiring a lethal dose, and the non-persistence of D.D.T. have to a considerable extent been overcome with those insects susceptible to it by scientific formulation and new and improved methods of application. One of us (F.G.S.W.), while carrying out trials at the Royal Naval School of Tropical Hygiene, Colombo, and later in this country, obtained excellent results against flies, mosquitoes, cockroaches, and bedbugs using the new activated emulsions evolved by Dr. H. Hurst, with greatly improved knock-down and residual toxicity. Using these emulsions there is little possibility of mosquitoes escaping from rooms with non-lethal doses, and the residual toxicity against cockroaches (among the most resistant of insects) has been proved to be effective for six months or more in such unfavourable surroundings as canteens and kitchens. Comparably good results have been obtained against flies on cattle.

The work of Twort¹ on heat volatilization of germicides has established the method of the production of insecticidal aerosols by a similar means. A continuous aerosol of D.D.T. produced by controlled heat at the rate of 20 mg. per hour per 3-5,000 cu. ft. (85-141 cu. m.) will give a complete knock-down of many diptera within 30 minutes or less. Furthermore, by this method the use of solvents is obviated and any loss of efficiency due to supersaturation is eliminated. What is of extreme importance is that a film of crystalline D.D.T. is continuously being deposited on all surrounding surfaces, and those which are highly porous will tend to have losses by absorption balanced by the continuous deposit of the aerosol. Even fabrics hung in a room in which a continuous-phase aerosol is being produced will, in time, become toxic to clothes moths.

With regard to cattle, field trials carried out last summer showed that the application of continuous-phase aerosols in the sheds for periods of as little as three hours daily gave immunity from biting flies both in the byre and at pasture.

The irritant effect of D.D.T. when not specifically formulated for quick knock-down may not in all cases be as harmful as may at first be apparent. Col. J. W. Scharfe, R.A.M.C.

when serving as the military member of the Medical Advisory Division, S.E.A.C., was of the opinion that relatively light contact by mosquitoes with walls sprayed with a 5% solution of D.D.T. in kerosene resulted in a "biting inhibition" reaction which prevented the insect from feeding, either by an initial peripheral paralysis or by loss of appetite caused by the D.D.T. This effect has been noted recently with the stinging of wasps in Sweden and with *Stomoxys* in this country.

Concerning the lack of toxic vapour we have clear evidence that vapours emanating from screened surfaces painted with D.D.T. are lethal to flies in enclosed spaces, though whether directly or by readsorption on to treated surrounds has not been determined.—We are, etc.,

Curare in Treatment of Spastic Conditions

SIR.—DRS. C. Astley Clarke and R. D. Hotston (Feb. 14, p. 289) report that curare in oil and wax had no advantages over the aqueous preparation in duration of effect or avoidance of side effects. With an air of finality they concluded that curare in oil is not the hoped-for advance in reducing spasticity.

With their findings one can have no quarrel. The implication that they have set up a critical comparable experiment with previous work is, however, fallacious. Their entire experiment was carried out with a suspension of *d*-tubocurarine in oil and wax supplied by Burroughs Wellcome and Co., whereas previous material was made up by the experimenter himself and later by E. R. Squibb and Sons. Suspensions in themselves vary with the techniques of the makers, and potency assays from manufacturer to manufacturer have varied greatly. This is common knowledge. There remains then a great weakness in the nature of your authors' conclusion from their experiments. A more acceptable and less sweeping conclusion would be that Burroughs Wellcome curare in oil and wax did not yield any more favourable results than aqueous curare.

I might add that spasticity is frequently a moiety of syndromes exhibiting weakness, ataxia, involuntary movement, and contracture. A critical evaluation, therefore, of its amelioration by any agent obviously requires careful study. Such study should include recording of range of motion changes, variations in stretch response as judged clinically and by myography, motion pictures of motor function, and whatever other data can be gleaned from the skills of the physiotherapist and neurologist. Static deformities must be exempted from the experimental group treated. Such data cannot be extracted from clinical observations of, "Did the injections enable a bed-ridden patient to walk or allow an ambulatory one to discard a stick?"—I am, etc.,

New York

EDWARD B. SCHLESINGER

Pancreatitis Due To Ascariasis

SIR.—I feel that this case is of sufficient interest to warrant a short description.

A boy of 18 months was admitted to hospital with a history of diarrhoea with blood and mucus, and a rectal prolapse, for three weeks. Examination showed a very thin baby with tense distended abdomen, liver slightly enlarged, a small readily reduced rectal prolapse, and temperature of 100° F. (37.8° C.). No other abnormality was found. The stools were very pale and bulky, offensive, and contained much free fat. They were unaffected by diet, and microscopy disclosed ascaris ova. The third day after admission a mass became palpable under the costal margin, just to the left of the midline, and antonin treatment produced two adult ascarides. Over the next eight days the mass slowly and steadily enlarged, with steady deterioration of the child's condition. The temperature swung regularly between 101° and 97.6° F. (38.3° and 36.4° C.).

On the ninth day after admission consent was at last obtained from the parents, and the mass was explored under local anaesthetic. An abscess cavity adherent to the abdominal wall was opened and 6½ oz. (190 ml.) of greenish-yellow pus with a sweetish smell was evacuated. The patient's condition precluding further exploration, a small drain was inserted and the skin protected with sterile vaseline. The following day there was a profuse yellowish serous

discharge and the drain was removed. The fourth day after operation slight digestion of the wound edges was noted, and the following day, the fifth after operation and the fourteenth after admission, the patient died.

Post-mortem examination disclosed an abscess cavity occupying the whole of the head of the pancreas, extending some 3/4 in. (1.87 cm.) to the left of the midline, and containing the partially digested remains of an adult ascaris. A track extended upwards retroperitoneally, entered the liver, the whole of the left and quadrate lobes of which were destroyed, and discharged through an incision at the left costal margin. In the small intestine a further seven ascarides were discovered.

In the rather limited literature at my disposal the only references I can find to a similar occurrence are those of ascariasis being a rare cause of acute pancreatitis in Craig and Faust, *Clinical Parasitology* (4th edition, 1945, p. 342), and Rose and Carless, *Manual of Surgery* (7th edition, p. 1314).

My thanks are due to the Acting Director of Medical Services, Tanganyika Territory, for permission to publish this account.

—I am, etc.,

Chuma, Tanganyika Territory.

N. A. DUNCAN.

Stasis of Chest Radiographs

SIR.—When a tuberculous patient moves from one district to another it is the practice of most tuberculosis officers to send the chest x-ray film to the colleague who is to take over the case, and these are often useful for comparison with subsequent films. The more enlightened voluntary hospitals also co-operate in this respect when they transfer patients to tuberculosis clinics. Sometimes, however, it is extremely difficult to obtain such films, not only from hospitals but even from Government departments.

It may be that this reluctance to part with x-ray films is due to the fear that they may be lost, but for practical purposes they may be just as much lost in the archives of some distant institution as if they were at the bottom of the Atlantic. True, some of these film-hoarders send clinical and radiological reports, but it is impossible to compare a film with a report. Surely when a patient moves from one clinic to another his chest x-ray film, often the one concrete piece of evidence in his medical history, should follow him like his more orthodox shadow.

The day draws near when the tuberculosis officer is to be enmeshed in the net of Governmental and voluntary hospital control, and he too may become a film-hoarder. Before the net is finally drawn, however, perhaps one last pleading wriggle may be permitted in this matter of the free circulation of chest x-ray films.—I am, etc.,

Worcester.

R. B. MAYFIELD.

Treatment of Undulant Fever

SIR.—The present unsatisfactory state of treatment of undulant fever is stressed in the annotation under this title in the *British Medical Journal* of Nov. 1, 1947 (p. 700), which prompts me to record my experience in the use of "suramin." ("germanin," "Bayer 205," or "antrypol").

Since it is rare for any one physician to have a sufficient number of cases under his care for a controlled experiment, and since the course of the disease is so unpredictable as to make conclusions drawn from a small number of cases hazardous, it is hoped that others will take steps to use this simple method of treatment and record their results, so as to confirm or refute its apparent efficacy.

So far as I am aware, suramin was first given for this purpose in 1930 by Dr. J. Leggate, of Salisbury, Southern Rhodesia, in consultation with me. The patient, an adult male European, had been ill for four months, and a blood culture revealed *Brucella abortus*, which his serum agglutinated to a titre of 1/50. The dosage was 1 g. suramin in 10 ml. of sterile distilled water intravenously once a week for four doses. The first dose caused some exacerbation of pyrexia and of symptoms, but after the second injection there was a gradual improvement, and convalescence began after the third dose.

Since that date the drug has been used by me for seven cases whose diagnosis had been definitely confirmed by positive blood culture. Satisfactory results were obtained in all of them.

The details of the procedure have varied somewhat, but the method now adopted is as follows:

As soon as a pyrexial period commences, 1 g. of suramin in 10 ml. of sterile distilled water is injected intravenously. This is usually followed by an exacerbation of symptoms and of pyrexia over the subsequent one to two days. A week later a similar injection is given. No exacerbation has been noted, and there is a tendency for the pyrexial curve to pass into a rapid lysis over the next two or three days.

In five of the patients a further pyrexial bout started and in these a further injection of 2 g. was given, with disappearance of all symptoms within 48 hours. In the other two cases two injections sufficed.

No treatment other than symptomatic was given, but in view of the well-known effect of suramin on the renal tubules the urine was examined daily for albumin and casts. On the above dosage neither was demonstrated on any occasion. The following is an illustrative case.

A European male aged 20 was admitted to hospital on Feb. 18, 1941, with a history of 6 days' headache, backache, shivering, and joint pains of insidious onset, the latter not relieved by adequate doses of aspirin; two days' drenching sweats, especially at night; sudden onset of acute pain, lasting for one day, in right knee, right hip-joint, left ankle, and left elbow, all of which were red, swollen, and distended with fluid.

On admission, T. 102.2° F. (39° C.), P. 128, R. 26; in extreme pain; appearance as of an acute gonococcal case with complications but no urethral discharge and no gonococci in prostatic smear. (There was a mild secondary anaemia, with W.B.C. 12,500 (polymorphs 68%, lymphocytes 30%, eosinophils 2%). Blood culture in broth and in blood-broth sterile. No agglutination to typhoid or *Brucella* groups on Feb. 19 and Feb. 24, 1941.

The treatment given was 1 g. sulphapyridine 4-hourly for 6 days, with an intramuscular injection of 1 g. soluble sulphapyridine twice daily on Feb. 19 and 20. This had no effect on the pyrexia, the acute joint pains, or the orchitis. By March 1 the temperature had returned to normal but the chart was "undulant" in character.

On March 4 a new pyrexial phase started and further blood cultures in blood-broth were taken. One specimen was incubated under normal conditions and one under 10% CO₂ tension; only the latter grew "an organism having the biochemical and agglutination reaction of *Br. melitensis*." On March 5 the first injection (1 g. suramin) was given intravenously. A mild exacerbation of pyrexia was noted but no increase in joint or testicular pain. On March 12 the second injection was given. There was no immediate effect, but from March 15 the temperature slowly subsided, to become normal on the 20th.

On March 23 the third pyrexial phase started and 2 g. of suramin was given on the 24th. During that night the testicular pain disappeared, but the joints were still very painful; temperature (8 p.m.) 102° F. (38.9° C.). The following day the temperature did not exceed 100° F. (37.8° C.) and was normal on the 26th. He was discharged from hospital on April 23 and was seen at intervals for nine months. No relapse occurred.

This case illustrates the following points: (a) the uncommon type with acute joint involvement; (b) the rare epididymo-orchitis (cf. Straus's reaction); (c) the failure of sulphapyridine; (d) the need for CO₂ tension for success in blood culture; (e) the method of treatment advocated.

Suramin is one of the symmetrical urea derivatives, and there is some laboratory evidence that it has an inhibitory action on the *Brucella* group.

A personal communication from Dr. M. Gelfand, of Salisbury, reports a further successful treatment by this method in a patient seen by him in consultation with Dr. Nuttall Smith, of Gloucester, who carried out the treatment.—I am, etc.,

S. R. SMITH, Government Medical Service.

R. M. MORRIS.

Idiosyncrasy to *d*-Tubocurarine Chloride

SIR.—May I comment on the article by Drs. T. Cecil Gray and John Halton (April 24, p. 784) on this subject? I was surprised to read that 15 mg. of *d*-tubocurarine chloride had been used on their first case as an initial dose. Surely there are very few anaesthetists who have not realized that such a dose is fatal. Previously I have advocated an initial test dose of 5-10 mg., followed by minimal additions, owing to individual idiosyncrasy (*British Medical Journal*, 1947, 1, 267). My own experiments have more than justified this belief.

I have also pointed out that when inflating the lungs must be done with care, namely, (1) distension of the stomach, (2) distension of the fund from the oesophagus to the airway, (3) distension of the airway, intubation in the majority of

cases is quite unnecessary with the glottis paralysed by *d*-tubocurarine chloride. However, it becomes essential when inflation is carried out, in order that a pack can be inserted in the pharynx or a cuff-tube in the trachea, either of which will avoid the above complications.

Blood-stained fluid was regurgitated and entered the air passages during the 195th minute, from which time the patient's condition appeared to deteriorate rapidly. The routine use of a cuff-tube or a pack before inflating the lungs would have avoided this catastrophe. However, it appears that in spite of this mishap Case 2 was again subjected to the danger of regurgitation into the air passages, not to mention the effect on the stomach of intermittent distension for 45 minutes.

I am in full agreement with Drs. Gray and Halton in re-emphasizing the importance of a trial dose, although I consider 1 mg. per stone sufficient as the initial dose for a child.—I am, etc.,

Swansea

D. S. JONES.

Malignant Syphilis

SIR.—Dr. C. D. Alergant (April 17, p. 757) appears to be critical of the medical memorandum written by Dr. W. Fowler and myself, entitled "Malignant Syphilis" (March 6, p. 457), and we would like to make the following comments:

1. The diagnosis was not at any time in doubt. In addition to the evidence in favour of syphilis which we published, the patient was also seen by Dr. J. T. Ingram, consulting dermatologist to the Leeds General Infirmary, who was also satisfied that the patient had syphilis. It is our experience, and that of most authorities we have consulted, that it is extremely difficult to find *S. pallida* in rupee or other very late secondary syphilitic eruptions.

2. We are accustomed to using very large doses of penicillin, arsenicals, and other drugs in the treatment of syphilis, but did not do so in this case because we were convinced that the slightest therapeutic shock would have precipitated his death. It was not merely a question of combating virulent infection but of endeavouring to keep alive a patient who from the time we made our first examination was almost moribund from severe and long-continued toxæmia.

3. It has been our experience that it is very difficult to infect rabbits with material from human syphilis. To have made this experiment when the patient was first seen would have meant subjecting him to unnecessary manipulations, thereby increasing his weakness.

4. The question of therapeutically inactive penicillin can be excluded because many other patients suffering from syphilis were treated with the same batch of drug, which was in general use in the hospital, and no suspicion of lack of potency was aroused.

Leeds

ROBERT LEES.

The Fenestration Operation

SIR.—With reference to the recent communications in your *Journal* on the above subject I should like to suggest that the newly formed Otolaryngological Group Committee of the B.M.A. should appoint a special research subcommittee from the most suitable members of the Group to collect the data submitted to them on request from all surgeons who have performed these operations. A national record should be kept of their results and the findings of this subcommittee should be issued through the *British Medical Journal* at regular intervals up to a period of ten years, so that the medical profession and, through them, the public will be able to reach a true assessment of the value of this operation in this country, being guided by such a body of experts. A questionnaire could be drawn up and sent out to cover all data required, both pre- and post-operative. Already much data is available compiled on a scientific basis.

I understand that Dr. Julius Lempert, of New York, who is shortly to pay us a welcome visit to this country, claims to have operated on several thousand cases, but we want to know the British findings. It was in this country that early pioneer work was done by Jenkins, Fraser, and the late Dr. A. A. Gray, before Mr. Lempert improved the technique and so made the operation practicable. The report would stimulate further research concerning otosclerosis, the cause of which is so little understood at present.

Medical opinion is much divided in this country, even among our most eminent specialists, as to the final results of this operation. Time is an essential factor. The success of this operation and its recognition by the medical profession depends

in Staphylococcal Infection

An ointment of proved value in staphylococcal infection, particularly syphilis barbae, syphilis vulgaris, and tinea sycosis, possessing noteworthy qualities for promoting tissue repair. Impetigo contagiosa is among other dermatological conditions which have responded favourably to "Quinolor" therapy. In 1 oz. and 16 oz. jars.

FORMULA

"Quinolor" (Chlorohydroxy quinolin) 0.5 gm., Benzoyl Peroxide 10.0 gm., Aromatic Oils 0.24 gm., White Petrolatum, Lanolin Anhyd. deod. 24 g.s. 100 gm.

COMBINED PROTECTION WITH 3 INJECTIONS

By the use of 'Wellcome' brand Diphtheria-Pertussis Prophylactic D.P.P., children may be immunised against the two diseases in a course of three injections. The product contains Diphtheria Prophylactic A.P.T. plus Whooping Cough Vaccine (Alum Precipitated). Immunisation with 'Wellcome' Diphtheria Prophylactic A.P.T. has markedly reduced the incidence of and mortality from diphtheria. Although Whooping Cough Vaccine does not confer a degree of immunity comparable with that induced by diphtheria prophylactics, wide experience amongst clinicians indicates its value in reducing the incidence and severity of the disease.

Vitamin Therapy *- its uses and limitations*

Nutrition in childhood

Loss of appetite and failure to thrive, the forerunners of more serious conditions of ill health in children, can sometimes be checked by nutritional adjustments. In this connection vitamins of the B complex are important. Vitamin B₁ is associated not only with the maintenance of appetite, but also with mental alertness: the complex as a whole is effective in controlling gastrointestinal motility; various skin complaints may be related to the need for extra supplies of the B₂ complex.

During the period of rapid growth and development, therefore, it is important to secure an adequate supply of all these factors and this can best be done by the use of a natural dietary supplement such as Bemax.

Bemax stabilised cereal embryo

1 oz. of Bemax provides approximately

vitamin B ₁	0.45 mg.	iron	2.7 mg.
vitamin B ₂		copper	0.45 mg.
(riboflavine)	0.3 mg.	protein	30%
nicotinic acid	1.7 mg.	available	
vitamin B ₆	0.45 mg.	carbohydrate	35%
vitamin E	8.0 mg.	fibre	2%
manganese	4.0 mg.	calorific value	104

GORDON C. HENRY.

The Nelson Touch

SIR.—“Serving Officer” (April 17, p. 750) need not worry over the revelation of names of V.D. cases to his commanding officer. He has not been in the R.A.F. long enough to forget he was once a doctor. Let him neglect to carry out this disgusting order. A colleague and I refused to comply with it when promulgated in this command six months ago. No direct action has been taken against us. Of course we should have been court-martialled and dismissed or even cashiered long ago. Our confidential reports must be close to the “adverse” level, though. That such a violation of confidence is performed uncomplainingly by the majority of medical officers is a sign of the times.—I am, etc.,

FLIGHT LIEUTENANT.

Colonial Medical Service

SIR.—From the Annual Report of Council (*Supplement*, April 10) at p. 94, it might be deduced that all that is wrong with the Colonial Medical Service is inadequate salaries. It appears also to be the Colonial Office view that since Colonial Governments cannot or will not pay more there is nothing to be done but hope that in time austerity and unemployment at home will force men into the service. But surely all medical men do not ask first where and how they can find most money?

In the colony that I have left private practice was probably better than in most others, and on average brought total incomes to a reasonable level. Yet the situation was (mid-1947): (i) The shortage of medical staff was between 30 and 40 on an authorized establishment of 99 all branches. (ii) The wastage from invalidings and resignations was unparalleled in any other department. (iii) Only about one in four entrants completed service to age 50. (iv) Many stations which used to have M.O.s were being worked by dispensers or nurses only; others no longer had M.O.H.s; the larger hospitals were badly understaffed. (v) Shortage compelled the retention in the service of passengers who brought discredit on it. (vi) Of the Government's promises to the people during the planning years of extended medical services, requiring a large increase in staff, nothing had come. (vii) Morale in the department was very low. All this, in spite of the facts that there is so much in the work of extraordinary interest, and so much in the life attractive to tough, enterprising, and restless persons; and that colonial was accepted as an alternative to military service.

I would suggest that the most important cause of the unpopularity of the service and the general dissatisfaction within it is the colonial civil service atmosphere in which we have to live and work, and the sort of administration and type of administrator we have to endure. Quite how soul-searing this is is difficult to describe briefly. To a remarkable degree the old tradition persists from the days when every man in West Africa had a “history” of treating staff rather as potential breakers of regulations and blotters of copy-books than as professional men doing work of some value.

For many years now the higher administrative appointments have with rare exceptions been filled from the numerically much smaller Health Branch—that is, by men who have spent almost the whole of their service in the relative ease and comfort of health offices, with little if any experience of the remote and lonely bush stations or of heavy work in the larger hospitals. Most of them soon develop a type of mind which makes inevitable disharmony between themselves and the working staff. Not long ago our head office staff were known collectively as the Old Men of Vichy. One director inspecting my hospital carefully examined the insides of all the drawers and cupboards, outside taps to see if they were leaking, and some disused latrines. That was all; of the work of the hospital, not a word. Another in the course of a little dispute barked out, “This is not a democratic service, it is a semi-military one.”

There is no freedom of expression of opinion, and the medical staff have no means of influencing either the Colonial Government or the Colonial Office. If the trouble is taken to draw up and present a memorial, it will merely get the usual dusty answer. If an individual criticizes or expresses opinions unwelcome in head office, he may be regarded as having permanently blotted his copy-book and forfeited all claim to consideration and promotion—and very likely be sent to a punishment station (I have been myself). A colleague who sent a brief signed letter to a journal drawing attention

to a misstatement in the advertisement was officially informed that he had thereby incurred the displeasure of the Secretary of State. Such offences are more serious than almost any degree of idleness or dissolute living.

In war it is realized that morale is all-important not only in the fighting services but among civilian workers. It is surprising and lamentable that it should have been so neglected in the Colonial Service. I see little hope of progress until there is installed as director-general at the Colonial Office one with a powerful personality who will be a great deal more than a mere Civil Servant and who will command the respect and the liking of the staff. At present there is only a small advisory staff consisting of retired administrators none of whom have ever meant anything to us in the Colonies.

Those who think there is nothing to fear in a whole-time salaried State service would do well to look closely at the Colonial Service. Not so long ago Dr. H. B. Morgan, M.P., then in opposition, alleged in the House that it was a disgrace. Very recently, supporting Mr. Bevan, he claimed that it was quite satisfactory. I think most of us would say he was nearer the mark first time.

As a retired (specialist) colleague remarked, it might have been a grand service, but the direction is all wrong. I have enjoyed it, and do not regret my choice, but would not now recommend it to one in search of a career unless he was very sure that his tolerance of “the direction” is and will remain without limit. Mine was not.—I am, etc.,

G. L. ALEXANDER.

Colonial Medical Service (ret.)

Bristol.

POINTS FROM LETTERS

Resident Appointments

UNEMPLOYED DOCTOR writes: During the present fantastic scramble for resident hospital appointments considerable time and anxiety could be spared the applicants if the following simple procedures were adopted by the hospitals concerned. (1) Appointments are only advertised if there is a definite vacancy not likely to be filled by a candidate already known to the appointing committee, or that the existence of such a candidate be indicated in the advertisement. (2) Appointing committees only short-list a candidate if they consider him fully suitable for the appointment, and not merely to make their meeting official. (3) Immediately the short list is compiled, candidates whose names do not appear on it are notified to that effect.

John Hilton

DRS. ELLIOT E. PHILIP and E. W. WALLS (Middlesex Hospital Medical School, London, W.1) write: We are preparing an entirely new edition of John Hilton's surgical classic *Rest and Pain* to be published by Messrs. G. Bell and Sons, Ltd., the publishers of the original lectures. We should be most grateful to any of your readers who can give us any information that might help us in this work. As we propose including a short biographical note on John Hilton we would welcome details of his life—especially his early life—and the temporary loan of any portrait that may be suitable for reproduction.

O.H.M.S.

DR. H. G. HOWITT (London, S.W.16) writes: I have already received complaints about the new method of dealing with national health certificates by the Ministry of National Insurance. One patient complained that correspondence with the Ministry over sickness certificates had cost a shilling in postage. In the past an insurance agent had called and paid cash. I advised her to let the Ministry pay postage in future.

Fainting at Immunization Sessions

DR. N. J. W. THOMPSON (St. Helens) writes: When carrying out diphtheria immunization on large numbers of school children I find that a certain number, say 2%, succumb to fainting attacks. . . . The attacks come on during, after, or sometimes even before inoculation. Nervous apprehension seems to be the provocative factor, and delicate or highly strung children seem the most susceptible. In dealing with such cases I find the following procedure very useful. I instruct the child to squat down, sitting on his heels. I then tell him to clasp his legs and press his thighs tightly against the abdomen. This manoeuvre, by squeezing the blood from the splanchnic area, raises the systolic and diastolic blood pressures by 15 to 30 mm. Hg. Cerebral circulation is quickly restored and the child recovers in a few minutes.

Festina Lente

DR. W. REGINALD WILSON (Doncaster) wires: Imperative retain ownership and settle about consultants and chemists and certification before assenting. Festina lente.

Obituary

ERIC GUTTMANN, M.D., M.R.C.P.

Eric Guttman was born in Gleiwitz, Upper Silesia, and spent the first half of his professional career in Germany. He came to this country in 1933. He died on April 25 at the age of 52.

Guttman's training, on his own initiative, was more than usually broad and thorough. After qualifying, he studied pharmacology before specializing in neurology in the clinically oriented school of neurology in Berlin under the leadership of Cassirer, Oppenheim's successor. He then went to Munich and studied psychiatry under Kraepelin and neuropathology under Spielmeyer. He became Lange's chief assistant at the Psychiatric Research Institute in Munich, and acting director there until he followed Lange to Breslau. With the beginning of the Jewish persecution he came to England in 1933 with the help of the Rockefeller Foundation. At the Maudsley Hospital he was one of the principal workers in the Department of Clinical Research until, at the outbreak of the war, like all others in his position, he was interned for a time. Subsequently he worked in the neurosurgical department at the Radcliffe Infirmary at Oxford and in the Neurosis Centre at Mill Hill Emergency Hospital. When the Maudsley Hospital was reopened he returned there and was assigned the arduous and anxious task of supervising the complete reorganization of clinical teaching there.

His chief work was in research and his main interests were in neuropsychiatry, in the investigation of the psychological phenomena of organic disease. His interests were wide. He was responsible for introducing the use of amphetamine in psychiatry, and his papers on the mesencephalic psychosis and on the artistic productions of psychotic patients awakened general interest. His work on the psychiatric aspects of head injuries was a permanent contribution to our knowledge. He did much other valuable work, on the functions of the frontal lobes, on meningiomas of the brain, on Schilder's disease, Huntington's chorea, the psychological aspects of general bodily illness, and on prognosis in schizophrenia. Social psychiatry, which came into prominence during the war, also engaged his attention. He was the psychiatric consultant to the Officers Selection Board of the National Fire Service, and later he carried out for the Ministry of Health an inquiry into the after-history of neurotic soldiers, the results of which have recently been published. His research work was characterized by catholicity of interest, breadth of learning, balance and coolness of judgment, and by thoroughness and caution.

Inevitably, as he was attached to a teaching hospital, he spent much time in teaching. From the time of his arrival at the Maudsley he exercised a considerable influence on his younger colleagues. Through him the Meyerian approach, which had been the dominant influence at that school, was broadened by phenomenological conceptions such as the possibility of analysing symptoms into those directly due to a basic organic process and those which represented a reaction of the personality. His clinical acumen and diagnostic powers were such as to give convincing evidence of the validity of the principles he taught. His teaching was seen at its best at the bedside, or in the discussion of fundamentals over coffee or tea. But he was an able lecturer, and he became part author of a well-known short textbook of psychiatry for medical students. Proud and declining any acknowledgment, he gave generously of his time in helping his junior colleagues with their work, whether it was research, the clinical problems of the ward, or aid from his knowledge of theory and extensive acquaintance with the literature. In his last years, when his chief occupation was the training of postgraduate students, he was able to attract and respect by his accessibility, his lucidity and his clinical wisdom.

As a man of such wide range and depth, there are men doomed to go through more than the average share of misfortune. Guttman was no exception. He was put in the first rank, yet he never lost his sense of his own limitations. His career was twice com-

again at the outbreak of war. Finally, when he seemed on the point of reaching the position his merits deserved, his health failed. Yet he was a man of genial and happy disposition. He gave all his loyalty to the land of his exile. With his deep kindness and self-effacing reserve he found himself at home in the temperamental pattern of English life. It was impossible not to be friendly with him. He met his misfortunes with the dry ironic humour and the courage and good will that marked his personality and endeared him to all who knew him. He is survived by the son and daughter of his first marriage, and by his wife, Dr. Elizabeth Rosenberg, and an infant son.

A.L. writes: No one could replace Eric Guttman in the affection of his friends, and it is very doubtful whether anyone can replace him in the remarkable contribution he was making to psychiatric research and the training of psychiatrists. From the time of his arrival at the Maudsley in 1934 it was clear that a man of outstanding capacity had come who was prepared to devote all his gifts, without thought of personal advantage, to the furtherance of sound psychiatry in this country. His integrity and friendliness, and the respect his abilities always evoked, soon made him a trusted adviser in all the clinical activities and the development of the medical school; every one of his colleagues learnt much from his unusual combination of sound, experienced judgment and fruitful scientific and therapeutic enterprise. He was versatile but never superficial; critical yet encouraging; and always to be relied on for unselfish, unlimited help. His tact and sure perceptions made him almost ideally successful in his dealings, whether with his colleagues, his pupils, or his patients and their relatives. When the Maudsley resumed its normal work after the war Guttman showed a characteristic disregard for his own interests and convenience. He knew, though his friends had no inkling of it, that he had a cardiac lesion which had given threatening signs, but he willingly shouldered a heavy burden of teaching and clinical duties; he enjoyed the work intensely, and many young psychiatrists have abiding reason to be grateful for the guidance and stimulus he gave them during those two post-war years at the Maudsley. So also have his senior colleagues. By his writings and research, and still more by his direct teaching and example, Guttman exercised upon the growth of psychiatry in this country a steady and increasing influence the full extent of which can hardly yet be appreciated. He gave this unsettled branch of medicine a sure impetus, brought it closer to neurology, and by his command of psychological and other research techniques, allied to wide clinical experience, showed the way of sound progress. But it is his generous spirit, his kindness, his humour and courage that his friends now remember with a feeling of intense personal loss.

Dr. CHARLES SHACKLETON SIMPSON, who was born at Brighton in 1861, died on April 21 at his home in Hove. He had retired from active practice some seventeen years ago. He had been bed-ridden for two years, and looked to his end with equanimity for he was unable to enjoy the fruits of his retirement, his garden, his books, and his music. He came of a talented family of architects, his father having designed much fine property in Brighton. Two other brothers were similarly engaged—one, Sir John Simpson, was P.R.I.B.A., and designed Wembley Exhibition and Roedean School. A third brother was professor of surgery at Sheffield. Educated at Brighton Grammar School, Charles Simpson studied medicine at Guy Hospital and qualified in 1889. After holding some junior appointments he settled in Hove, where he practised for forty years. He did much hard and useful work and was greatly loved and respected by all. He gave unfailing courtesy, kindness, and consideration, and had a quiet bedside manner together with a keen sense of humour. He refused to argue or get ruffled, thus preserving a peace of mind which he loved in his household and fireside. Rush and hurry were foreign to him, though he always had time for everything. For many years Dr. Simpson took a great practical interest in a local Scout troop. He was a keen naturalist and ornithologist and was interested in photography. He was a great reader, and also had a magnificent library of gramophone records. Throughout his career there were no outstanding honours or publicity, no display, just plenty of hard work. He had many an interesting and amusing tale to tell of past decades when walking, horseback riding, cycling, and carriages preceded cars. He also told of typhoid, which was very common in the old days, and of the period when teeth were extracted with an

instrument like a key, the operator keeping his top hat on during the process and the tooth jumping up to the ceiling.

When he retired many mourned his going and inquired about him long afterwards. Charles Simpson had a broad tolerance and understanding of new ideas and youth, together with a practical knowledge of clinical medicine. He had the true Christian spirit. Sympathy is offered to his wife, who looked after him so well in health and sickness, and to his two daughters.—J. H.

Dr. WILLIAM FRANCIS CHRISTIE, who died at Stibbington on April 25, was the son of the late Dr. Dugald Christie, C.M.G. He came from a large family, of whom a number entered the medical profession, including Prof. R. V. Christie, of St. Bartholomew's Hospital, and Dr. J. M. Christie, of Finchley. Coming from Edinburgh with an outstanding athletic record, and after a not undistinguished academic career, Christie first entered the R.A.M.C. as a regular officer. He served with distinction during the 1914-18 war and in India. He had graduated M.B., Ch.B. in 1909, and he proceeded M.D. in 1919. On retirement in 1923 he went into practice in Lancaster Gate, London, where he remained until recalled to serve as a medical specialist during the 1939-45 war. At the end of the war he did not return to practice but retired to a beautiful old rectory near Peterborough. At one phase of his career Christie became interested in obesity and was the author of two popular books on this subject. These were a happy combination of scientific fact and cynical humour, presented in a language which could be understood by the laity and illustrated by a famous artist with drawings which emphasized how much the lusts of the flesh contributed to a pathological state. "Willie" Christie was a first-class tennis player and was a regular tournament competitor until the last war. He had a large circle of friends, both inside and outside the profession. He was a natural host, a charming companion, and a good friend to many. In his practice he combined kindness and tact with shrewdness and ability. These characteristics were invaluable to him in dealing with his many important patients, to whom he often had to give unwelcome advice. He is survived by his widow, Cecil, daughter of the late Sir Abe Bailey, whom he met when she was nursing during the 1914-18 war. There were no children.—L. W.

Medico-Legal

LIBEL ACTION BY MR. MATTHIAS ALEXANDER

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

The evidence given during the first nine days of the hearing of this action for libel was reported in our issue of March 20 (p. 575). The plaintiff was Mr. Frederick Matthias Alexander, of London, and the defendants were three medical men, Dr. Ernst Jökl, Physical Education Research Officer to the Union Education Department, Dr. E. H. Cluver, Director of the South African Institute for Medical Research at Johannesburg, and Dr. B. Maule Clark, of Houghton, Johannesburg, as editors of *Manpower*, a biannual scientific journal published in Pretoria by the Government Printer and circulating throughout the Union.

Mr. O. Pirow, K.C., addressed the court for the defence.¹ It relied, he said, on the plea of prescription, that the action had been brought after the statutory period of one year had expired; and on the pleas of justification and fair comment. The evidence showed that Mr. Alexander was an ignorant layman who knew very little of anatomy and physiology yet claimed that healing or therapeutics was "his own province." His five books were useless as textbooks for his technique or as guides to health or to a philosophy of life. They could be read only as "sales talk." They tried to eliminate all possible sources of competition as incomparable or harmful. As against the "incompetence" of the medical world, the "humbug" of faith healing, and the "quackery" of physical education, Mr. Alexander claimed that his technique was unique, that it had a practical procedure that would prove the keynote of future evolution, and that its practice would eradicate and prevent all disease. This he supported with the equally revolutionary contention that all disease really originated in erroneous preconceived ideas of the use of the body and the self. Mr. Pirow submitted that these claims had been completely disposed of

by the medical evidence. If his claims to provide an unfailing preventive to disease were held to constitute quackery, then disposed of the case.

The fact that Mr. Alexander might improve posture by manipulation and provide other qualified benefits was beside the point. His claims covered the whole field of pathology from cancer to hay-fever. The evidence about the technique boiled down to achieving a certain posture and receiving certain manipulations; from these and a certain head-neck relationship certain remarkable benefits were claimed, but there was no evidence properly establishing a relation between the action and the alleged benefit. Sir Henry Dale had given evidence that the support of such eminent laymen as Sir Stafford Cripps and the late Lord Lytton could be looked upon as "a typical instance of group hystero-neurosis." Most of Mr. Alexander's cures seemed to have affected people afflicted with some form of anxiety neurosis.

Case for the Plaintiff

Mr. H. J. Hansen, K.C., submitted for the plaintiff that the article complained of was a complete misrepresentation of the principles of Mr. Alexander's teaching.² It omitted all references to the method of teaching—the inhibition of the old wrong manner of use and the substitution of a new right use in which the head-neck relationship was of prime importance. Nor was there any reference to the theme that the results of this right posture and body mechanics would correct old strains and misuses and would strengthen man's resistance and thus in time make him immune to disease. Dr. Jökl was not concerned with Mr. Alexander's claims in their medical or educational aspect, but only as they affected physical education, of which he was a protagonist. The setting in which the article was written was the suggestion that Mr. Alexander was making false claims about the benefits of his system on health as compared with physical education. If this interpretation of the article was correct, it was curious that Mr. Alexander's claims to prevent disease bulked so little in the article but loomed so large in the evidence for the defendants. The whole suggestion was that Mr. Alexander was dishonest, but Dr. Jökl had said under cross-examination that he had no grounds for calling him dishonest. Not a tithe of evidence had been brought for the defence on the physical side—all the big guns had been brought to bear on the medical side. Even on that side witnesses of the highest standing had given evidence that Mr. Alexander had never claimed to cure or treat in the medical sense. They had all testified to the benefits received. Against this, the defendants and their witnesses had acknowledged that they knew nothing about the practical technique on which Mr. Alexander's claims were based but were none the less prepared to say it was all nonsense. The statement that in time the Alexander technique would provide an unfailing preventive of disease was obviously, in its context, one of Mr. Alexander's dreams of the future. It was just a hypothesis, like Dr. Cluver's, that many of man's ills came from depression and worry. There was overwhelming evidence that Mr. Alexander had specifically disclaimed any attempt to diagnose or cure diseases, and that where people had gone to him for treatment or cure he had sent them off with a flea in their ear and told them that that was a matter for a doctor.

Judgment

In a fifty-page written judgment Mr. Justice Claydon analysed the evidence given in Johannesburg and on commission in England and gave his conclusions in detail. These conclusions he summarized.³

Mr. Justice Claydon said that the defendants had shown that Mr. Alexander was a quack in the sense that he made ignorant pretence to medical skill. They had shown that much of the physiological reasons put forward were wrong and that in its claim to cure the Alexander system constituted dangerous quackery. In these matters, however, they had misrepresented the views of Mr. Alexander. In showing how foolish were those views which he did not put forward they had in the article in *Manpower* called him much more of a quack than they were entitled to do. In addition the defendants had failed, in his view, to prove that the Alexander system could not bring about the results claimed in the improvement of health and the

prevention of disease; again, they had made matters worse by overstating the claims made for the system. Discussing next the allegation of quackery in the field of physical education, the judge said that on the facts of the case it was Mr. Alexander's claim to improve health, not the claim to cure or prevent disease, which related to physical education. The claim to improve health had not been shown to be baseless, even in the medical field. As against the finding of the court being partly in favour of the defendants, counsel for the defence argued that if it was shown that there was quackery, and dangerous quackery, that was the sting of the article and the plaintiff would not then be entitled to an award of damages. This contention was not, in his view, well founded in law. Although he did find dangerous quackery shown in some respects, that did not put an end to the plaintiff's claim on this ground. Apart from the fact that in the present case there were charges of fraud and dishonesty—even if these were confined to the fraud and dishonesty inherent in quackery—this was a case where in substance the defendants had called the plaintiff a much worse quack than they could prove to be true. Mr. Justice Clayden then cited instances in support of the contention that the justification should be as broad as the libel.

The defendants had said that there was quackery in the field of physical education and dishonest quackery in the field of medicine, both in claims to cure and in claims to prevent disease and improve health. They had proved only quackery and dishonest quackery in the sense that quackery is always dishonest in the claim to cure. Even in that regard they had made the quackery appear to be worse than it was and they had alleged dishonesty to a greater degree than would be implicit in quackery itself. In these circumstances, too, the justification was not as broad as the libel. What the defendants had proved would assist them in the question of mitigation of damages, but it did not constitute a defence to the action. There was no evidence to justify the allegations of dishonesty in the wider sense which were imputed by the article in *Manpower*.

The two other defences set up in the defendant's plea were prescription and fair comment. It had not been argued that the action was prescribed, the evidence showing that the plaintiff came to know of the article less than a year before the issue of the summons. Nor was it necessary to deal at length with the defence of fair comment. There were so many facts in the article which were not true, either in the sense that there had been misdescription of the technique or because only part of the facts had been set out, that the foundation for the defence of fair comment had not been laid.

On the plaintiff's contention that the article was published with malice on the part of Dr. Jokl, its author, the judge said: "If that question has to be considered, it is, I think, only right to say that I think the truth of Dr. Jokl's evidence, should it come into question, is a matter with which his demeanour has nothing to do. There was nothing in his demeanour in court which gave me the impression that he was being anything but truthful."

Mr. Justice Clayden concluded, therefore, that the plaintiff was entitled to an award of damages. Although the circulation of the article had been small, it had nevertheless been circulated to important and influential readers, and the circulation had not been confined to South Africa. Bearing this in mind he had to decide what damages should be awarded for a defamation which had in part been shown to be the truth but which had throughout overstepped the mark, which in a large part of the attack had not been proved to be true, and which had involved additional allegations of dishonesty and criminal conduct which were not justified.

Throughout the article scathing terms were used. The article was intended to be emphatic in its showing up of what the author regarded as a real danger. When an attack was made in such terms and was not wholly justified, those responsible could not expect an award of merely nominal damages. He considered that proper award in all circumstances to be £1,000. The defendant was ordered to pay the costs of the action, including the costs of the application to take evidence on commission and the costs of taking that evidence.

Medical Notes in Parliament

RADIOACTIVE SUBSTANCES BILL

In the House of Lords on April 29 Lord HENDERSON moved the Second Reading of the Radioactive Substances Bill. The main provisions of the Bill were summarized in our issue of April 24 (p. 812).

Lord Henderson said that a Bill with the same purpose had been introduced about a year ago but was found to be capable of improvement. Improvements suggested then had now been accepted. Radioactive substances were used in industry as luminizing agents and in the manufacture of other products. Radium and radon were employed in treating certain forms of cancer. Powerful x-ray tubes were used industrially, for example, for testing castings. Artificial radio-elements would shortly become available and would be of immense importance as research tools and for therapeutic purposes. Possible injuries to health if these substances were handled without stringent precautions ranged from minor burns to serious illness and death. Undue exposure to radiation might have genetic effects which as yet were uncertain. A good deal had been achieved by the British X-Ray and Radium Protection Committee appointed over twenty-five years ago by the Medical Research Council, but its advice had not always been asked or taken.

Artificial radioactive substances would soon be available in considerable quantities. More powerful x-ray apparatus was being developed. The cyclotron, the betatron, and the synchrotron, though potent tools in the hands of the scientist and the doctor, added greatly to the need for protection. Parliament must protect the worker in industry or in hospitals, the patient who ran the risk of unskilled treatment, and the public at large. In the Bill the substances and apparatus concerned and the methods of protection required were left to be laid down in Regulations. It was a difficult and complicated technical matter, to draw a line between dangerous and harmless amounts of radiation, and the Government must be able by Regulations to frame appropriate definitions and apply them on expert advice. Proceeding by Regulation would facilitate amendment to meet changing circumstances in a field in which new discoveries were being made daily.

Advisory Committee

Clause 6 required Ministers to appoint an Advisory Committee after consultation with appropriate organizations which would include the Medical Research Council, the Royal Society, the Physical Society, the three Royal Colleges, and the three Corporations in Scotland, the Faculty of Radiologists, the Department of Scientific and Industrial Research, and the British X-Ray and Radium Protection Committee. In each case the Minister concerned was required by the Bill to consult this Committee before making Regulations, which must also be published in draft form.

The Bill proposed in Clause 3 to prohibit the sale or supply to the public of medicines or toilet preparations containing more than a prescribed quantity of radioactive material, except by a doctor or dentist holding a licence for the purpose from one of the Health Ministers or by a chemist under the authority of a prescription from a licensed doctor or dentist. Clause 3 also limited the administration of radioactive substances to licensed doctors and dentists. This was proposed because the Government was advised that the dangers inherent in many of these new substances were not universally known even among members of the medical profession.

Clause 4 required anyone using irradiating apparatus emitting radiation of a strength to be defined in Regulations for medical or dental treatment to obtain a licence from the appropriate Minister. The Government knew of many unfortunate accidents the repetition of which it intended to prevent. The Clause provided for the extension of licensing to cover the use of the apparatus for diagnostic purposes if that course was advised by the expert advisory committee. This Committee would advise on the appropriate qualifications and experience on which licences were to be granted and on conditions to be attached to the grant. Both Clause 3 and Clause 4 empowered the Ministers to exempt specified classes of persons from the requirement to obtain a licence, any such exemption being dependent on consultation with the Advisory Committee.

Safety Precautions

Clause 5 empowered the Minister to make by Regulation codes of safety precautions for the protection of the public and workers in premises where radioactive substances and

irradiating apparatus were used. Regulations relating to factories in which luminizing was carried on were already in force and had been found most useful. There were other establishments for which safety precautions should be prescribed—for example, hospitals and laboratories. In addition the Minister was empowered to ensure by Regulation that radioactive waste products from factories and so on were disposed of safely. Chimneys should be heightened to ensure that dangerous smokes were dissipated; the rate and temperature at which liquid effluent was discharged should be regulated; and contaminated articles of clothing or equipment should be disposed of safely.

Clause 1 empowered the Minister of Supply to manufacture, process, and distribute radioactive substances. This would enable him to dispose of by-products from atomic energy piles as well as natural radium and radon. The Government hoped to improve the supply of radioactive substances of all kinds for medicine, research, and industry. Clause 2 gave the Minister power to control the import and export of radioactive substances, a control at present effected under a temporary Act of 1939. Lord Henderson closed by emphasizing the Government's intention to avoid unnecessary interference with science, medicine, or industry.

Lord CHERWELL said that for the last twenty-five years there had been scarcely any cases of severe injury to persons using x rays. When one compared the relative safety of this sort of work with the number of deaths on the road one felt that perhaps Parliament was taking unnecessary trouble. On the other hand a number of new radioactive substances were being produced and the carrying into law of some measure such as the Bill was probably justified. He was glad that the Bill introduced last year had been replaced by the new measure. The old Bill was calculated to hamstring research. This Bill laid down that nobody, unless he had a licence, was to administer a radioactive substance to human beings. On that the Minister presumably would act on the advice of the Committee. No definition was given in the Bill of "irradiating apparatus." This too would have to be decided on the advice of the Committee. He hoped the Minister would make sure that the Committee contained industrial people who used these substances and that it was not over-weighted with medical watchdogs.

Lord AVULREE said this was the first time that any form of control of the use of x rays had been placed upon members of the medical profession. It would now become necessary for a doctor to obtain a special permit before he could carry out certain forms of treatment. He hoped that requirement would not become a regular practice, but he admitted that the danger to patients from the use of radium and x rays by medical practitioners who had not been well trained and experienced in their use was very great. He had seen catastrophic instances where people had been severely damaged by radiation. The Bill said a person carrying on a hospital, a clinic, or a nursing home could possess radioactive substances. He asked whether sufficient care would be taken to ensure that matrons could not acquire radium or other radioactive substances and keep them in such a way that proper protection was not afforded. He was pleased to see that safeguards would be provided in hospitals and factories. It would be valuable to control more buildings where radioactive substances were used, although these buildings did not come under the Factories Act.

Lord HENDERSON said physicists would have proper representation on the Advisory Committee. He was not able to say whether there would be industrial representatives. It would be within the province of the Industrial Committee to make recommendations about the conditions in which stocks of radioactive substances should be held in hospitals and nursing-homes.

The Bill was read a second time without a division and was sent to a Committee of the whole house.

Personal Injuries Bill

Sir HARTLEY SHAWCROSS moved on April 23 the Second Reading of the Law Reform (Personal Injuries) Bill. He said Clause 1 abolished the notorious doctrine of common employment whereby an employer was not responsible for injuries to his servants caused by the negligence of a fellow servant. A subsequent Clause provided that in assessing the sum to be awarded to an injured workman the courts should in future take into account his loss of earnings or profits but should set against that loss one-half of the National Insurance benefit. The courts would continue to have regard to medical expenses if these had been incurred. There would be no obligation to incur such expenses after the National Health Scheme came into operation, but if they were nevertheless incurred they would rank.

The Bill was read a second time.

Criminal Justice Bill

The LORD CHANCELLOR, in the House of Lords on April 27, moved the Second Reading of the Criminal Justice Bill, into which the House of Commons had inserted a provision suspending the execution of a capital sentence for five years. In the course of the debate the BISHOP OF WINCHESTER said Parliament had experience of other measures which were hurried forward without regard to the times. The National Health Service might for a time deprive people of medical assistance with the intention of some day providing medical assistance for all. Lord OAKSEY did not think any classification of murders or of murderers would be of benefit. It was far better to leave the matter at the discretion of the Home Secretary.

When the debate was resumed on April 28 Lord TEMPLEWOOD said the Bill proposed greater facilities for medical inspection and treatment of prisoners, on the basis that penal prisoners had to be dealt with individually. Investigation of individual cases and the adoption of the method most suitable for the particular delinquent had succeeded in the Fighting Services during the war. He felt profoundly the need for this country to show its respect for the sanctity of human life. Lord READING mentioned the substitution in the Bill of the term "Broadmoor patient" for "criminal lunatic." That exemplified the tendency in this country to call things by a different name and think that thereby their character was changed.

Lord MAUGHAM predicted that if capital punishment were suspended there would in five years be practically no difference in the number of murders. The experiment would prove nothing. A large proportion of those who spoke in the House of Commons against the death penalty did so because of the method of its administration. The method was out of date, horrible, and caused hysteria among prisoners who heard that a hanging was taking place. With modern knowledge a mere prick in the arm would surely carry out the course he held, in the interest of the State, to be necessary.

Lord BALFOUR OF BURLEIGH said he found in the Bill a provision for compulsory mental and physical examination. He understood it to be a principle of common law that an accused could not be physically examined without his consent. He believed that little could be gained from a physical examination except with the co-operation of the prisoner. He felt the proposal departed from the principles of established law. It was also a new principle of law that an innocent person should be forcibly made to give a finger-print.

The Bill was read a second time and referred to a Committee of the whole House.

Industrial Injuries—The National Insurance (Industrial Injuries) Bill was read a first time in the House of Commons on April 29.

Hospital Beds—Sir ERNEST GRAHAM-LITTLE inquired on April 30 how many hospital beds in England and Wales would be available on the appointed day as compared with the number in 1938. Mr. BEVAN replied that the total number of beds in England and Wales at the end of 1947, the latest date for which information was available, was 533,000. The corresponding figure for 1938 so far as known was 466,000.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

Field-Marshal the Rt. Hon. Jan C. Smuts will be installed as Chancellor of the University on June 10 and will afterwards confer honorary degrees, including that of D.Sc. on Sir William Wilson Jameson, K.C.B., M.D., F.R.C.P., Chief Medical Officer, Ministry of Health and Ministry of Education; on Sir Hugh Lett, K.C.V.O., C.B.E., F.R.C.S., President of the British Medical Association; and on Sir Paul Fildes, O.B.E., M.B., B.Ch., F.R.S., Director of the Department of Chemical Bacteriology, Medical Research Council. The same honorary degree will be conferred also on Sir Robert Robinson, D.Sc., President of the Royal Society and Waynflete Professor of Chemistry in the University of Oxford.

UNIVERSITY OF GLASGOW

On April 24 the degree of M.D. was conferred upon J. Hood, Colonel J. S. K. Boyd, late R.A.M.C., and R. R. Gordon.

UNIVERSITY OF EDINBURGH

Prof. Robert McWhirter, the first occupant of the recently endowed Forbes Chair of Medical Radiology, delivered his inaugural lecture in the Pollock Memorial Hall, Edinburgh, on April 28, when he was introduced by Prof. Sydney Smith, acting Principal of the University. His subject was "Some Biological Reactions to

The Defenders of Human Rights are organizing a discussion at the National Health Service, to be held in the Kensington Town Hall at 8 p.m. on Wednesday, May 19. Admission is free. The professional point of view will be put by Dr. D. A. Ferment of Mr. John Bunyan. Other speakers include Dr. Letitia Fairfield, Dr. H. B. Morgan, M.P., Mr. Wilson Harris, M.P., and Mr. I. Pitman, M.P.

Surgeon to Lecture in Hungary

Mr. A. E. Porritt will visit Hungary to lecture on behalf of the British Council between May 16 and 29. He will speak on penicillin in surgery, gastrectomy, and injection treatment of hernia.

Association of Doctors' Wives

The Association of Doctors' Wives (Birmingham and district) has been formed under the presidency of Prof. Hilda Lloyd with the broad intention of enabling doctors' wives to meet and discuss matters of particular interest to them, and to encourage them to take an interest in municipal and public life. The annual minimum subscription is 5s. Doctors' wives in and around Birmingham may obtain information from the Secretary, Mrs. L. H. Chittis, 353, Chester Road, Castle Bromwich, Birmingham.

Medicine in War

The Medical Research Council has issued a report entitled *Medical Research in War* (H.M.S.O., price 7s. 6d. pp. 455). The Council was required to advise the Government during the war on a great variety of medical problems, many of them arising directly from the conditions of warfare. Its success in one field at least is revealed by the high chance of survival of a British soldier wounded in battle—93%. The report outlines the many investigations initiated and conducted by the Council. It will be discussed in a future issue of the *Journal*.

Committee on Partnerships: Evidence Invited

The committee set up recently by the Minister of Health to consider whether Sections 35 and 36 (affecting partnerships) of the N.H.S. Act need amending will receive evidence from any organization or persons directly interested. Memoranda should be submitted to the Secretary of the Committee, Ministry of Health, Whitehall, London, S.W.1, as soon as possible, and in any case before the end of May.

Physician Emigrating

Dr. H. L. Wallace, physician at the Royal Edinburgh Hospital for Sick Children and lecturer on child life at Edinburgh University, is emigrating to South Africa to help organize a health service in Natal.

Postgraduate Surgery

The Royal College of Surgeons has prepared a scheme for providing residential accommodation for postgraduate students. The local authorities have approved the plan. Reconstruction of the College will probably start this year.

Golf Competition

The Middleton and North Manchester Medical Society are holding a competition on Wednesday, May 12, at the North Manchester Golf Club. Particulars may be obtained from Dr. J. A. Strachan, 566, Broadway, Chadderton (Tel. FAI 2230).

COMING EVENTS**St. George's Hospital Medical School**

Lecture-demonstrations in neurology and psychiatry will be given in the large lecture theatre of St. George's Hospital Medical School, Hyde Park Corner, London, S.W., on Thursdays, at 4.30 p.m., from May 6 to July 22, both dates inclusive. They are open, without fee, to medical practitioners and senior medical students.

Royal Medico-Psychological Association

The next quarterly meeting of the Royal Medico-Psychological Association will be held at Dublin on Wednesday and Thursday, May 12 and 13. The programme is as follows: At Royal College of Physicians of Ireland, Kildare Street, May 12, 10.15 a.m., business meeting. 11 a.m., Drs. J. Kearney and T. W. H. Weir, "Legislation and Mental Health." 2.15 p.m., Mr. John Hayward, "The Personality of Dean Swift." 5 p.m., reception at country branch of St. Patrick's Mental Hospital, at St. Edmundsbury, near Lucan, as part of the bicentenary celebrations of Swift's hospital (St. Patrick's). At Grangegorman Hospital, May 13, 10.15 a.m., Dr. J. Dunne, "A Ten Years' Survey of Physical Methods of Treatment." 2.15 p.m., Dr. H. J. Eustace, "Addiction under the Mental Treatment Act, 1945." 8 p.m., reception by the President of Eire at his residence in Phoenix Park.

Edinburgh University Club of London

The 238th dinner of the Edinburgh University Club of London will be held at the Savoy Hotel on May 20, with H.R.H. the Duke of Edinburgh as guest of honour and Sir John Anderson, P.C., M.P., in the chair. The dress for the occasion will be evening dress with decorations. Members should have received notification of the function, but any who have not are requested to communicate with the honorary secretaries, Edinburgh University Club, 12, Wimpole Street, London, W.1.

London School of Hygiene and Tropical Medicine

The annual meeting of the Court of Governors of the London School of Hygiene and Tropical Medicine will be held at the school (Keppel Street, Gower Street, W.C.) on Wednesday, May 19, at 4 p.m.

Tuberculosis Association

A meeting of the Tuberculosis Association will be held at Birmingham on Friday and Saturday, May 21 and 22. On May 21, at 2.30 p.m., at the Queen Elizabeth Hospital, a communication on "The Clinical Estimation of Cardio-respiratory Function" will be presented by Prof. W. Melville Arnold, Dr. A. G. W. Whitfield, and Dr. G. H. Armistage, and at 4.20 p.m. Dr. Francis Jarman will speak on "The Clinical Significance of Bronchial Lesions in Pulmonary Tuberculosis." At 7.30 p.m. a reception and dinner will be given by the Lord Mayor of Birmingham at the Council House. On May 22, at 9.30 a.m., at the English Theatre, The University, Edmund Street, Dr. A. Clark Penman will present a communication on "Primary Tuberculosis in the Adult"; at 10.30 a.m. Dr. J. F. Geddes and Mr. A. L. d'Abreu will discuss "Selection of Cases for Thoracoplasty"; and at 12 noon a colour film, made by Dr. Paul H. Hollinger, of St. Luke's Hospital, Chicago, on "Bronchial Tumours, etc. as seen at Bronchoscopy" will be shown. Mr. Geoffrey Bateman. The annual conference of the association will be held at Belfast on June 30, July 1, 2, and 3.

New Schools

An exhibition entitled "New Schools" will be open to the general public from May 26 to June 19 at the Royal Institute of British Architects. Examples of school furniture from several European countries as well as Britain will be exhibited.

Pathological Society of Great Britain and Ireland

The meeting of the Pathological Society of Great Britain and Ireland, which had provisionally been arranged to take place at Ghent on July 9 and 10, has had to be cancelled owing to currency restrictions. The meeting will take place in the Medical School, Leeds, on the same dates.

SOCIETIES AND LECTURES**Monday**

EDINBURGH UNIVERSITY: PHYSIOLOGY CLASSROOM.—May 10, 5 p.m. "Religion and Medical Progress," by Dr. Douglas Guthrie.

INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY, 330, Gray's Inn Road, London, W.C.—May 10, 6 p.m. Cinematograph films: "Organic Disorders of the Larynx" and "Bronchial Neoplasms," by Mr. Geoffrey Bateman.

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, Cavendish Square, W.—May 10, 8 p.m. Annual general meeting, 8.30 p.m. "The Line of Drugs," Annual Oration by Dr. A. H. Donthwaite.

Tuesday

CHELSEA CLINICAL SOCIETY.—At South Kensington Hotel, 41, Queen's Gate Terrace, London, S.W., May 11, 7 for 7.30 p.m. Annual dinner of the 51st Session of the Society.

INSTITUTE OF DERMATOLOGY, 8, Lisle Street, Leicester Square, London, W.C.—May 11, 5 p.m. "The Lichenoid Eruptions, including the Neurodermatoses," by Dr. R. M. B. MacKenna.

INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY, 330, Gray's Inn Road, London, W.C.—May 11, 2.15 p.m. "The Respiratory Tract in Infectious Diseases," by Dr. E. H. R. Hargis.

UNIVERSITY COLLEGE LONDON: DEPARTMENT OF PHYSIOLOGY.—At Physiology Theatre, Gower Street, London, W.C., May 11, 5 p.m. "The Physical Aspect of Speech," by Mr. D. B. Fry, Ph.D.

Wednesday

GLASGOW UNIVERSITY: DEPARTMENT OF OPHTHALMOLOGY.—May 12, 8 p.m. "Disturbances of the Lacrimal Apparatus," by Dr. James Hill.

BRITISH ASSOCIATION OF PHYSICAL MEDICINE.—At Royal College of Surgeons of England, Lincoln's Inn Fields, London, W.C., May 12, 5 p.m. Discussion: "Physical Methods in Geriatrics," to be opened by Mr. L. Cosin and Dr. Marjory Warren.

Thursday

CHADWICK TRUST.—At University College, University Park, Nottingham, May 13, 4 p.m. "Advances in Preventive Medicine during the War of 1939-45," by Sir Arthur MacNalty.

EDINBURGH ROYAL INFIRMARY.—May 13, 4.20 p.m. Honyman Gillespie Lecture: "On Abdominal Pain," by Mr. F. R. Brown.

UNIVERSITY COLLEGE LONDON: DEPARTMENT OF PHARMACOLOGY.—At Physiology Theatre, Gower Street, London, W.C., May 13, 5.15 p.m. "Permeability and Drug Action," by Mr. J. F. Danielli, Ph.D., D.Sc.

Friday

ROYAL INSTITUTION, 21, Albemarle Street, London, W.—May 14, 9 p.m. "The Role of Chemistry in Combating Tropical Diseases," by Sir Ian Heilbrunn, F.R.S.

APPOINTMENTS

Mr. Commodore H. A. Hewat, C.B.E., M.B., Ch.B., D.T.M.&H., has been appointed Medical Adviser to the British Red Cross Society and has taken up his duties at the society's headquarters at 14, Grosvenor Crescent, London, S.W.1.

Prof. H. W. Rodgers, F.R.C.S., and Mr. J. A. W. Bingham, F.R.C.S., have recently been appointed to the surgical staff of the Infant Hospital for Sick Children.

D. VINCENT, E. A., M.S., F.R.C.S., Surgeon to Orthopaedic and Traumatic Unit, West Middlesex County Hospital.

Mr. DAVENPORT took the London degree with honours in 1932 and the M.S. in 1935. During the war he served as a surgeon specialist in the R.A.M.C. He has contributed papers on "Swelling of the Upper Limb following Radical Mastectomy," "Infection of the Hand," and "The Control of Staph. aureus in an Operating Theatre."

J. GAY, T. E. D., M.B., Ch.B., M.R.C.P., D.C.H., Paediatrician to West County for Cheshire County Council, Chester Corporation, and Chester Royal Infirmary.

GROVER, V. O. B., M.R.C.S., L.R.C.P., D.P.H., D.I.H., Deputy Medical Officer of Health, County of Oxfordshire.

Hospital for Sick Children, Great Ormond Street, London, W.C.—Assistant Medical Officer (Radnor Court), Elspeth M. Frith, M.B., B.S., House Officer, William Roe, M.B., B.S., House Physicians, J. A. Black, M.B., B.Ch., M.R.C.P., and F. W. Nash, M.B., B.S., M.R.C.P.

LOVING, JEAN, M.B., Ch.B., Assistant Psychiatrist, Crichton Royal Mental Hospital, Dumfries.

Middlesex County Council.—The following senior appointments are announced: W. Hirston, M.D., M.R.C.P., D.P.H., Deputy County Medical Officer of Health, K. R. Stokes, M.R.C.S., L.R.C.P., Medical Director, Harefield Hospital, R. Asher, M.D., M.R.C.P., Physician, Central Middlesex County Hospital, C. H. Dunn, M.R.C.S., L.R.C.P., D.A., Senior Anaesthetist, West Middlesex County Hospital.

Ministry of National Insurance.—The following appointments have been made to the headquarters medical staff of the Ministry of National Insurance: Deputy Medical Officer, F. M. Collins, Ch.M., F.R.C.S., J. M. Davidson, M.D., D.P.H., C. J. P. Grosvenor, M.B., B.Chir., Senior Medical Officer, W. D. T. Hooper, D.M., D.P.H.

MURRAY, D. I., M.B., Ch.B., D.P.H., Assistant Senior Medical Officer, St. Andrew's Regional Hospital Board.

PURVIS, W. J., M.B., B.S., D.A., Honorary Consulting Anaesthetist, Royal Victoria Infirmary, Newcastle-upon-Tyne.

SHARP, C. G. KAY, M.D., Honorary Director, Contact Lens Unit, Royal Eye Hospital, London, and King's College Hospital, London.

STEWART, J., M.B., Ch.B., D.P.M., Deputy Medical Superintendent, Park Royal Hospital, Basingstoke.

THOMAS, J. C. S., M.R.C.P., D.P.M., Regional Psychiatrist, North-East Metropolitan Regional Hospital Board.

WILLIAMS, J. I., M.D., Director, Pathological Department, Royal Infirmary, Sheffield.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Borthwick, On March 10, 1948, at Fernwood House, Jesmond, Newcastle-upon-Tyne, to Betty (née Flinn), wife of Dr. I. Borthwick, 25, Redewater Road, Leamington, a son, David James.

Frank, On April 28, 1948, to Marjorie (née Hutton), wife of Dr. H. Frank, 1, W. St. John and Lippin, a daughter.

Hillingsworth, On May 1, 1948, at Sheffield, to Cynthia Hillingsworth, M.B., M.R.C.P., wife of Prof. R. S. Hillingsworth, M.D., F.R.C.P., a daughter.

Kitchin, On April 11, 1948, at 265, Langley Road, Slough, to Jean (née B. C. D.), wife of Dr. A. P. Kitchin, a daughter.

Mundy, On April 25, 1948, at Cleveland Nursing Home, Paddington, W., to Betty (née Hill), wife of Dr. P. Gordon Mundy, 152, Plashet Road, London, E. 1, a son, Anthony Richard.

Pugh, On April 23, 1948, at Redruth, Cornwall, to Daphne, wife of Dr. J. I. Pugh, a son, Michael James.

Stradling, On May 1, 1948, at Central Middlesex County Hospital, to Peggy (née Brown), wife of Dr. Peter Stradling, a son.

Thomas, On April 27, 1948, to Joyce, wife of Stanley F. Thomas, M.B.E., F.R.C.S., of G. Padman, Ganjam District, Orissa, India, a daughter—Edith Margaret.

DEATHS

Osborne, On April 25, 1948, at the Old Rectory, Subbington, near Peterborough, to William Francis Osborne, M.D., formerly of Lancaster Gate, London, W.

Clark Wilson, On April 29, 1948, at 2, Roseburn Cliff, Edinburgh, John Clark Wilson, M.D., M.R.C.P., F.R.C.S., D.P.H., aged 77.

Coburn, On April 27, 1948, at West Middlesex Hospital, Brentford, James L. Coburn, F.R.C.P.S.I., F.R.P.S. Glas., of White Lodge, Bedford, aged 43.

Conran, On April 27, 1948, Philip Crawford Conran, M.D., of Firgrove, Macclesfield, Cheshire, aged 63.

Frankel, On April 25, 1948, Ernest Maurice Frankel, M.D., of 10, Devonshire Road, London, W.

Hartman, On April 25, 1948, John Herbert Hartman, M.D., of Southport, Lancs.

Hughes, On April 25, 1948, at Ch. H. House, Leicester, Gloucester, Staffs, Arthur Hughes, M.B., Ch.B., M.R.C.S., L.R.C.P., aged 60.

Thomas, On April 25, 1948, at Llanelli, Carmarthen, Cynl Herbert Thomas Hutt, M.B., Ch.B., M.R.C.P., aged 41.

George, On April 25, 1948, at Eastern Nursing Home, Dundee, George George, M.B., Ch.B., F.R.C.S., of The Times, Carmarthen, Angus.

Stewart, On April 25, 1948, at 1, Victoria Road, Glasgow, M.R.C.S., L.R.C.P., aged 60.

Tudhope, On April 25, 1948, at 1, Victoria Road, Glasgow, J. James Tudhope, M.B., Ch.B., M.R.C.S., L.R.C.P., aged 60.

Wright, On April 25, 1948, at 1, Victoria Road, Glasgow, P. H. Wright, F.R.C.S., aged 60.

Wright, On April 25, 1948, at 1, Victoria Road, Glasgow, P. H. Wright, F.R.C.S., aged 60.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended April 17.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland. Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland. A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Measles and whooping-cough are not notifiable in Scotland, and the return are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

|| Includes puerperal fever for England and Wales and Eire.

EPIDEMIOLOGICAL NOTES

Provisional Death Rates for 1947

The decline in the maternal mortality rate in England and Wales continued during 1947, resulting in a new low figure of 1.01 per 1,000 total live and still births, compared with the previous lowest rate of 1.24 in 1946. The rate per 1,000 total live and still births for deaths from abortion was 0.17.

A male rate of 593 deaths from respiratory tuberculosis per million civilian population maintains the fall that has taken place since the high figure of 795 in 1941 and 611 in 1946. The corresponding rate for females increased from 344 in 1946 to 362 in 1947. The rates for other forms of tuberculosis were 87 for males and 72 for females.

Deaths from cancer among females continued to increase, the rate per million civilian population being 1,745, compared with 1,735 in 1946 and 1,577 in 1937. The rate for males from this cause was 1,976, compared with 1,987 in 1946.

Discussion of Table

In England and Wales decreases in the number of notifications were recorded for measles 1,512, acute pneumonia 64, and diphtheria 19, while an increase was reported for whooping-cough 585 and scarlet fever 94.

The largest decreases in the incidence of measles were London 449, Surrey 273, Middlesex 132, Lancashire 116, and Derbyshire 114. Notifications of whooping-cough are about twice the usual average and are the highest since 1941; during the week the largest increases were Lancashire 107, London 55, and Cheshire 52.

A small rise in the incidence of scarlet fever in most areas of the country arrested the decline that occurred during the preceding five weeks. There were no local variations of any size in the returns of diphtheria.

Three cases of paratyphoid were notified from the cities of Birmingham and Dewsbury. While a fall in the notifications of dysentery was recorded in other areas a rise occurred in London from 18 to 30 (Camberwell 14) and in Yorkshire West Riding from 17 to 28. The only other large return for dysentery was Lancashire 24.

Notifications of acute poliomyelitis were 5 more than in the preceding week. The only administrative districts with more than one case were Leicestershire, Barrow-upon-Solr R.D. 3, and Essex, East Ham C.B. 2.

An outbreak of gastro-enteritis in Scunthorpe, Lincolnshire, has caused the death of 13 babies under 12 months during the past five weeks.

In Scotland the incidence of measles decreased by 130, while small increases were reported for scarlet fever 14 and whooping-cough 16. The notifications of dysentery in Glasgow were 7 more than in the preceding week.

In Eire a decrease in the notifications of measles 34 and primary pneumonia 14 was recorded, while the notifications of whooping-cough increased by 34. The decrease in measles and the increase in whooping-cough were fairly general throughout the country.

In Northern Ireland the only change in the trends of infectious diseases was a decrease of 7 in the notifications of diphtheria.

Week Ending April 24

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,535, whooping-cough 3,727, diphtheria 179, measles 9,092, acute pneumonia 593, cerebrospinal fever 43, acute poliomyelitis 16, dysentery 252, paratyphoid 3, and typhoid 4. One case of cholera, a laboratory infection, was notified.

The Council on National Emergency Medical Service of the American Medical Association held its spring session recently and discussed medical aspects of modern warfare and its problems of sanitation and general hygiene. There were lectures on atomic, chemical, and psychological warfare. Dr. Edward L. Bortz, President of the A.M.A., said that it was necessary to collect information on the management of casualties caused by biological products and chemical agents. American medicine had never faced a greater challenge, and the A.M.A. was determined to function through its various councils in every way it possibly could for the protection of the nation's population. Dr. Wigodsky emphasized the necessity for nation-wide education about atomic energy so that people should have a factual basis for reasonable logical thought on the matter. Dr. G. F. McGinness, vice-president for health services of the American National Red Cross, outlined the organization prepared for combating disaster. The Red Cross scheme includes the provision of medical supplies, equipment, and staff, and the establishment of shelters for victims who have had their houses destroyed.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Sarcoidosis

Q.—What are the current views on the causation, symptomatology, and treatment of sarcoidosis? In what way does it differ from Darier-Roussy sarcoid?

A.—Some of these problems were discussed at the International Conference of Physicians held in London in September, 1947. An absolute cause is not known but many authorities regard sarcoidosis as a particular pattern of reaction in the tissues consequent upon sensitization (the term "anergic" is used) to a chronic infection. This may be a tuberculous infection in this country (leprosy, coccidioides, etc., in other countries), but the organism is not demonstrable and the Mantoux reaction is commonly negative. The skin lesions are most easily assessed, but similar infiltrations occur in other organs in relation to the reticulo-endothelial system. Focal or nodular, plaque or sheet infiltrations of a lupoid character are seen in the skin and may be observed in tonsils or be appreciated by palpation in deeper subcutaneous tissues, glands, liver, spleen, tendon sheaths, etc. They may be detected in the lungs and in the bones, especially of the hands and feet, by x-ray examination. A "chilblain circulation" may favour deposits about the nose, cheeks, ears, hands, and feet, producing a condition described as lupus pernio, which is nearly always associated with lesions in bones, lungs, and other tissues. In the experience of the writer and of others the response of calciferol in large dosage (100,000 units daily for an adult) is quite remarkable, but there is no constant response to other measures. The histology is markedly tubercloid, and essentially presents masses of endothelioid cells with no surrounding infiltration or disorganization of collagen and rarely any tendency to caseation or giant-cell formation.

The so-called Darier-Roussy sarcoid is ill-named and bears no direct relationship to this syndrome. It is a variant of Bazin's disease, a gummatous tuberculous process associated with deep induration in the subcutaneous tissues and usually affecting the lower legs.

Failure to Ovulate

Q.—What is the likely cause of failure to ovulate? Is any treatment likely to help? The patient I have in mind is a married woman of 28, with a history of apparently normal and regular periods. On being investigated for infertility she was told that an endometrial biopsy showed no secretory phase. What is the prognosis? She is very anxious to have a baby.

A.—The cause of failure to ovulate in the absence of gross pelvic disorder is unknown, and its occurrence is so common that it can be regarded as being almost physiological. Since one cycle may be anovular, ovulation occurring in other cycles, the result of a single endometrial biopsy may be of little significance. In this case it would be desirable to repeat the endometrial biopsy during several cycles, or to instruct the patient in the keeping of charts of the daily waking temperature (vaginal, rectal, or oral) to see whether menstruation is regularly anovular. Alternatively, the estimation of the excretion of pregnanediol during the second half of several cycles might be helpful. Only when it is established beyond doubt that anovular menstruation occurs so commonly that it is likely to be the real cause of the infertility is treatment indicated. Treatment is in any case difficult, and the results are not easy to assess because of the ever-present possibility of a spontaneous return of ovulation.

The best hope of precipitating ovulation probably lies in the application of cyclical gonadotrophin therapy by Hamblen's technique. This consists in giving ten daily intramuscular injections of 400 units of serum gonadotrophin, followed by ten daily intramuscular injections of 500 international units of chorionic gonadotrophin. The first injection should be given

on the 10th day of a 28-day cycle (counting from the first day of menstruation). Ovulation is most likely to occur after the 10th day, and injection of chorionic gonadotrophin, and coitus should be timed accordingly. Treatment should not be given more than two consecutive cycles. If pregnancy does not occur the treatment should be repeated only after an interval of several months.

Thiopentone and Laryngeal Spasm

Q.—In actual practice is there any great danger of laryngeal spasm from inducing anaesthesia with intravenous thiopentone ("pentothal") and following up with ethyl chloride and open ether? Would you use this method in the absence of a machine?

A.—Most anaesthetists have the impression that thiopentone increases the liability to laryngeal spasm during induction of anaesthesia. As is the case with most respiratory depressants, a spasm once initiated relaxes but slowly. To minimize the risk of spasm the induction dose of thiopentone should be kept to a minimum and the subsequent ethyl chloride and ether should be administered with the same skill and artistry as though no thiopentone had been given. In these circumstances laryngeal spasm is rare. The risk of spasm is still further reduced if the larynx is sprayed with cocaine before administering the thiopentone. The thiopentone-ethyl chloride-ether sequence is quite satisfactory with the open mask. In fact, during the war thiopentone and ethyl chloride became a favourite method of induction before ether anaesthesia with the Oxford apparatus, a method virtually equivalent to an open mask.

Repeated Haematemesis in Polycythaemia

Q.—Can any treatment be suggested which will control repeated haematemesis and the intermittent passage of large amounts of uric acid gravel in a case of polycythaemia? Deep x-ray therapy has given only temporary benefit. Venesection once a week has helped to control the haematemesis, but has not affected the urinary condition.

A.—Repeated haematemesis in polycythaemia is usually due to peptic ulceration, which is present in about 8% of patients with this disorder. In a smaller group polycythaemia is associated with cirrhosis of the liver (Mosse syndrome). It is of importance, therefore, to determine the cause of the haemorrhage in this particular instance and, if peptic ulceration is present, to treat it on the usual medical lines. The passage of uric acid gravel is the result of the increased urinary excretion of urates accompanying the raised level of uric acid in the blood that characterizes this disease. This can be checked only by controlling the hyperplastic process itself, and the effective means of accomplishing this are irradiation of the entire skeleton, injections of nitrogen mustard, and injections of hydrophorus. The last-named is not yet available in this country, and the second produces only short remissions. A copious intake of water and alkalis should help to prevent the precipitation of urates.

Varicose Ulcers

Q.—A woman aged 58 has had severe varicose ulcers of the lower leg for a year and a half years. Blood Kahn and W.R. are negative. The organisms responsible are a "coliform organism" and *Staph. aureus* (penicillin-sensitive). Various local applications have been tried without effect. The ulcers have become much worse. She has been treated with ointment of zinc oxide and has had no effect. She refuses to go to bed for the night, as she did so once, and when she did so the ulcer disappeared. Should amputation be considered? I should much appreciate advice concerning this case.

A.—Amputation should never be considered in ulcers due to varicose veins. The first consideration is to treat the varicose veins by ligation and excision, if these veins are not too numerous. If the ulcer becomes easier, the treatment of the ulcer becomes easier. If the ulcer is due to old femoral thrombosis, then supportive treatment is all that is needed. The ulcer will often succeed when

applied with great tightness and with pads of adhesive felt or "sorbo" over the ulcer itself. Another way to get a good support is to keep the patient in bed during the week-end and on Monday's visiting round apply Unna's paste, renewing this bandage each time with a preliminary two-days rest in bed. Another alternative is to apply Thiersch grafts to the ulcers with the patient in bed for four weeks. After healing, appropriate support must be continued—permanently, if necessary. It may take the form of Unna's stocking, elastic bandages, or elastic stockings, according to the amount of scarring of the leg and the tendency to oedema.

Shrunk Breasts

Q.—A woman of 35 breast-fed her second baby for eight months, then went on holiday without the child and developed much engorged breasts. She was treated first with stilboestrol and then changed to belladonna plasters and tight bandaging, which relieved the pain. There were no ill effects at the time, but now the breasts have shrunk. Can you recommend any treatment to restore her original form?

A.—It is very unlikely that stilboestrol or belladonna plasters, etc., could have more than a temporary effect, and probably the breasts will recover spontaneously. Stilboestrol inhibits lactation by suppression of the pituitary lactation hormone, but, apart from the period of lactation, it normally has a stimulating action on breast structure. The local inunction of ung. oestradiol or stilboestrol might be tried. It is assumed that menstruation has now returned to normal and there is no evidence of wider endocrine dysfunction—e.g., delayed pituitary superinvolution.

Egg-grown Vaccinia Virus

Q.—Has experience confirmed the impression that post-vaccinal encephalitis may be avoided by the use of egg-grown virus for vaccination instead of the usual lymph preparation? Are supplies yet available in this country?

A.—Insufficient numbers of individuals have been inoculated with egg-grown vaccinia virus to provide any evidence regarding the risk of post-vaccinal encephalitis from such a vaccine. In one small trial by Buddingh in the U.S.A. the lesions in 9 children inoculated with vaccinia virus grown on the chorio-allantoic membrane were milder than in 10 children who received calf lymph vaccinia virus. The neutralizing antibodies were of the same titre in both groups, one month and fourteen months after vaccination. Vaccinia virus grown on the chorio-allantoic membrane of developing chick embryos is not in current use in any country so far as is known. Further trials and improvements in production are necessary before the large-scale use of such a vaccine can be considered.

NOTES AND COMMENTS

Naming Drugs.—Mr. T. C. BLACK (Menley and James, Ltd. London) writes: "Mr. Lloyd (April 17, p. 757) raises a point of some interest to us. We are arranging to make supplies of 'mandelamine' (which, unfortunately, must be known here as 'mandamine' available in this country, and have decided to use the description methenamine mandelate. We considered anglicizing this description but as this is a new drug and methenamine is a B.P. synonym we considered it preferable to retain the original American description and to shun the confusing practice to which Mr. Lloyd rightly draws attention in the last paragraph of his letter."

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: Allford Western, London. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the British Medical Journal alone unless the contrary be stated. Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required, as proofs are not sent abroad. ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m. TELEPHONE: EUSTON 2111. TELEGRAMS: Britmedads, Western, London. MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association, TELEPHONE: EUSTON 2111. TELEGRAMS: Medisecra, Western, London. B.M.A. SCOTTISH OFFICE: 7, Drumhugh Gardens, Edinburgh.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY MAY 8 1948

INSURANCE ACTS COMMITTEE

A meeting of the Insurance Acts Committee was held on April 22, with Dr. E. A. Gregg in the chair. The members, as trustees of the National Insurance Defence Fund, received a report from the Treasurer, Dr. J. W. Bone, that five more areas had completed their quota towards the target of one million. A discussion took place on the future of the funds accumulated by statutory and voluntary levies respectively. The Chairman said that moneys under the statutory levy could be used only for administrative purposes, and any balance when the Panel Committee was wound up would have to be handed over to the Practitioners' Fund. Concerning the voluntary levy, apart from cases in which an individual committee making the levy had stated that the money should be used in certain ways, each committee could do what it pleased with the fund, subject to the liability to repay to a contributor who demanded it the portion of his contribution which was unexpended.

Dr. Wand presented the revised draft statement of evidence on certification under the National Health Service Act which it is proposed to give to the departmental committee. The draft had been prepared by a joint committee of the Insurance Acts and General Practice Committees. The committee agreed to certain amendments made by the revising body. The principal discussion took place on the reference in the evidence to the increasing number of certificates which practitioners are asked to complete in support of applications for passports, tobacco concessions for old-age pensioners, and other non-medical purposes. A strong recommendation had been included in the draft that practitioners should be relieved of this burden by the deletion of the reference to the medical profession from the classes of persons—barristers, schoolmasters, relieving officers, and others—authorized to sign such certificates.

This recommendation was opposed by some members of the Insurance Acts Committee, who felt that the family doctor should perform this relatively slight service for his patients, and that it would cause a certain amount of inconvenience to them if he did not. Eventually an amended recommendation was agreed to, to the effect that practitioners should be relieved of this burden so far as possible. Dr. Wand and his sub-committee were complimented on their work in preparing this evidence.

A report of a discussion between certain representatives of the Committee and the National Insurance Advisory Committee on the Maternity Benefit Regulations was also received.

The Committee considered the various resolutions carried at the recent Special Panel Conference. On the motion by Cumberland that any contract of terms of service should be not one-sided as contemplated but two-sided, and that the Minister should not have power to add to or alter the terms without consultation and agreement with the profession, Dr. Dain said that in interviews at the Ministry it was stated that under National Health Insurance the profession had always been consulted (except on one occasion, by an oversight, for which an apology was made), and they could only say that that should be continued.

The motion by Derbyshire passed at the Conference calling for an undertaking by practitioners who felt compelled to take service under the Act that they would refuse to accept patients or dependants of patients now on the lists of doctors who had

refused to come in was also considered. The Chairman said that it would be perfectly legitimate to ask such practitioners to give such an undertaking, and the matter had been referred to the trustees of the Independence Fund. On another matter arising from a resolution by Hull that practitioners be advised not to accept any medical cards under the Act unless so advised by the British Medical Association, it was stated that the Independence Fund trustees had been into this matter with great care and had decided upon an appropriate plan of action.

The Committee expressed their support for the views of the Council of the B.M.A. as expressed in the statement issued in connexion with the second plebiscite.

HEARD AT HEADQUARTERS

Coroners and the Doctor's Duty

Two coroners gave interesting addresses when they were the guests at dinner of the West London Medico-Chirurgical Society. Mr. H. Neville Stafford, coroner for the London Western district, remarked that for a long time it was held that there was some legal obligation on a doctor to report a death to the coroner. The matter was eventually referred to counsel (Sir Roland Burrows), who gave his opinion that no such obligation existed, the only legal duty in this respect being imposed on the registrar. It might have been supposed, said Mr. Stafford, that after this medical practitioners would say, "Very well, we have no legal obligations, and there is no penalty, so we will let the registrars do it." But in fact, to the great satisfaction of the coroners, doctors are still ready—at least in Mr. Stafford's experience—to report to the coroner as before, and in practice counsel's opinion has made no difference. If doctors do report to the coroner it certainly expedites matters and saves the relatives some trouble. The other coroner, Mr. H. G. Broadbridge, whose jurisdiction is the western district of Middlesex, mentioned that of 13 full-time coroners in England and Wales 11 are medically qualified. Under the Act of 1926 a coroner is required to be either a barrister or a solicitor or a legally qualified medical practitioner of not less than five years' standing in his profession. Mr. Broadbridge said that it was easier for a doctor to obtain sufficient knowledge of law to enable him to discharge his duties properly as a coroner than for a lawyer to obtain sufficient knowledge of medicine, for in law a great deal has to be studied on theoretical lines, whereas medicine is based more on practical work. He gave one or two examples of certificates which had come his way containing errors which might very well not have been spotted by a coroner who had not had a medical qualification.

A Token of Appreciation

A sum of 50 guineas has lately been put into the Charities Trust Fund of the Association. This was an amount sent to the honorary secretary of the North Northumberland Division by the Divisional General Manager of the North-Eastern Region of the Railway Executive at York as a tangible recognition by the former L.N.E.R. of the work performed by members of the local medical profession on the occasion of the accident some time ago at Goswick in Northumberland.

Association Notices

COUNCIL OF THE B.M.A.

Election of 22 Members by Grouped Branches in the British Isles, of 2 Public Health Service Members, and of 1 Woman Member

The following have been elected for the session 1948-9:

East Yorkshire and Yorkshire Branches:	L. Dougal Callander, Doncaster.
Bedford, Bucks and Oxford, Birmingham, and Staffordshire Branches:	J. A. Brown, Birmingham.
North Wales, and Shropshire and Mid Wales Branches:	J. A. Ireland, Shrewsbury.
South Wales and Monmouthshire Branch:	W. V. Howells, Swansea.
Bath, Bristol and Somerset, Gloucestershire, Worcestershire and Herefordshire Branches:	H. M. Golding, Bristol.
Kent and Sussex Branches:	R. P. Liston, Tunbridge Wells.
Edinburgh and Fife Branches:	J. G. M. Hamilton, Edinburgh.
Glasgow and West of Scotland Branch (Glasgow Division):	W. M. Knox, Glasgow.

The following candidates have been nominated:

Isle of Man, and Lancashire and Cheshire Branches:	R. Kennon, Liverpool. D. R. Owen, Chester. F. M. Rose, Preston. J. Cottrell, Grimsby.
Derbyshire, Leicestershire and Rutland, Lincolnshire, and Northhamshire Branches:	E. C. Dawson, Derby.
Northshire, Cambridge and Huntingdon, Essex, Hertfordshire, Norfolk, Northamptonshire, and Suffolk Branches:	G. O. Barber, Dunmow. J. C. Pearce, Diss. J. S. Ross, Welwyn Garden City.
Metropolitan Counties Branch:	J. A. Gorsky, London. F. Gray, London. Lord Horder, London. A. M. A. Moore, London. H. H. D. Sutherland, London.
Devon and West Hants, South Western and Wiltshire Branches:	G. F. Burnell, Truro. J. A. Pridham, Weymouth.
Sussex and Surrey Branches:	A. C. de B. Helme, Guildford. N. E. Waterfield, Little Bookham.
Aberdeen, Dundee, Northern General, of Scotland, and Perth Branches:	Mary Esslemont, Aberdeen. J. T. Simpson, Perth.

and papers will be issued to the members of these Groups on May 15, 1948.

Nominations have been received for Group A (North of England); Group Q (Border Counties, Glasgow and West of Scotland (Five County Divisions), Stirling); Group R (Northern Ireland).

PUBLIC HEALTH SERVICE

The following have been elected: James Fenton (Kensington); R. H. H. Jolly (Wolverhampton).

WOMAN MEMBER

Ernest Atken (London), being the only candidate nominated for election by women members, is elected as a member of Council for 1948-9.

CHARLES HILL,
Secretary.

Diary of Central Meetings

MAY

1. V. Council, 10 a.m.

Branch and Division Meetings to be Held

Metropolitan Counties Branch.—At B.M.A. House, Tavistock Square, London, W.C.1, Tuesday, June 1, 2.30 p.m. Ninetieth Anniversary Meeting. Agenda: Report of Branch Council for 1947-48; Report of Branch representatives on Central Council, 1947-48; election of officers for 1948-9; address by incoming President.

East of London Division.—At City Hall, Charing Cross, London, E.C.4, Thursday, May 13, 7 p.m. Annual Meeting. Agenda: Report of Division of Representatives to Council for 1947-48; Report of Division representatives on the Public Health Committee; election of officers for 1948-49; and (2) Annual Meeting of the Division.

B.M.A. ANNUAL MEETING

CAMBRIDGE, JUNE 25 to JULY 2, 1948

When completed, the following form should be sent to the Executive Officer, Local B.M.A. Office, Guildhall, Cambridge.

Form of Application for Accommodation

NAME (Block Letters).....

ADDRESS (Block Letters).....

I hereby authorize you to book on my behalf the accommodation detailed below and I undertake to pay for it in advance. (The rates are: Colleges £1 2s. daily with full board; Town Lodging 9s. daily, Bed and Breakfast.)

.....Single Room(s) (male) from the night of.....
till the morning of.....

.....Single Room(s) (female) from the night of.....
till the morning of.....

.....Double Room(s) from the night of.....
till the morning of.....

I would prefer Room in *.....College
or in Town Lodgings*

*State College preferred or Town Lodgings

Signed.....

Date.....

Please give the following additional particulars:

Are you a graduate of Cambridge?.....

If so, what College?.....

Do you intend to bring a car?.....

Which Scientific Sections do you propose to attend?.....

Please remember to bring Ration Books or Emergency Ration Cards, Towels, and Soap. When booking is completed an account will be sent to you.

TICKETS AT CAMBRIDGE ANNUAL MEETING

With reference to the notice about tickets which appeared in the *Supplement* of April 24 (p. 108), will members please note that these are not obtainable in advance but should be obtained on registration at the Guildhall on arrival at the Meeting.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar.
Non-County Borough Councils.—Dartford, Radcliffe (limited to future appointments), Tottenham, Wallsend.

Urban District Councils.—Denton, Droylsden, Houghton-on-Spring, Huyton-with-Roby, Portslade, Redditch (restricted to new appointments), Tyldesley.

Scottish Burghs.—Motherwell and Wishaw.

The Home Office announces that Dr. Richard Morton Geldart is no longer authorized under the Dangerous Drugs Acts to be in possession of or to supply dangerous drugs.

LONDON SATURDAY MAY 15 1948

AETIOLOGY, DIAGNOSIS, AND TREATMENT OF EARLY VITAMIN-DEFICIENCY STATES

BY

Z. A. LEITNER, M.D.

Clinical Assistant, St. Mary's Hospital, London

Vitamins are chemically and structurally heterogeneous organic compounds, and their functions—so far as they are known—differ even more. They are produced either in negligible amounts or not at all in the human body, do not furnish energy, and are not utilized as building units for the structure of the organism: they are able to perform their complicated functions in the transformation of energy and for the regulation of metabolism in minute quantities.

Following the spectacular advance in vitamin research, clinical medicine has not been able to keep pace with the laboratory. For the same reason we know now a larger number of different vitamins than identified human deficiency syndromes. Naturally occurring avitaminosis is mostly due to multiple deficiencies, and therefore controlled animal experiments with deprivation of one single vitamin cannot easily be translated to human beings.

Aetiology of Vitamin-deficiency States

The causes of vitamin-deficiency states are either primary or conditioned.

Primary Deficiency.—Nutritional deficiency states of the tissues may be caused solely by inadequate diet, and this is termed primary deficiency. Primary deficiency states are comparatively rare in this country at present. They are, however, occasionally seen in single old people who are either unable to collect their food or to cook it properly, or in persons with self-imposed restriction of essential food intake (Leitner, 1948a). By "dietary inadequacy" is meant the failure to ingest an essential nutritional factor in sufficient amounts to meet the existing body requirements. "Nutritional inadequacy" means not only the failure to ingest (i.e., dietary inadequacy) but failure to absorb and to utilize essential nutritional factors in sufficient amounts to meet these requirements. "Nutritional failure" occurs when essential nutritional factors fail to reach the tissues and the protective mechanisms of the body are unable to compensate the malnutrition. At that point symptoms begin to appear. The factors responsible for inadequate intake (primary deficiency) are poverty, ignorance, improper cooking and preparation of food, and self-imposed restriction of essential food (faddiness, eccentricity, anxiety).

Secondary or Conditioned Deficiency.—Nutritional deficiency states occurring on adequate dietary intake are known as secondary or conditioned deficiency. The importance of conditioning factors as a cause of deficiency states has not always been sufficiently recognized. Even when gross manifestations of deficiency disease caused by conditioning factors are recognized the findings may lead to one of two errors (Jolliffe, 1942): (1) to consider the lesion a manifestation of the original or conditioning disease unrelated to tissue depletion (e.g., to attribute polyneuropathy to pyloric stenosis); (2) after recognizing the nutritional basis of the secondary manifestation, to attribute the original disease solely to nutritional deficiency (e.g., in the case of a middle-aged edentulous woman to ascribe the symptoms only to malnutrition, disregarding the loss of teeth, the often associated dysphagia, achlorhydria, etc.). The first error ignores the existence of deficiency disease, the second

ascribes most deviations from normal health to malnutrition only.

These conditioning factors are: (a) interference with ingestion; (b) interference with absorption; (c) interference with utilization; (d) increased body requirements; (e) increased excretion; and (f) increased destruction.

Interference with Ingestion

The inclusion of this as a conditioning factor is warranted owing to the frequency with which abnormal conditions and disease may interfere with adequate food intake. For example in hospitals the food intake is often calculated from the meals served to the patients. It is common knowledge that even convalescent hospital patients consume only a part of the meals as served (DuBois and Chambers, 1942). Our experts similarly calculate an adequate food intake for the population in this country. It is, however, very probable that the monotony of our diet for the last six to seven years, the lack of choice, and the fact that the population's very limited variety in food depends more on the chance of the food available on the world market than on their taste may be considered as a conditioning factor. For a considerable part of the population on the relatively low protein and fat and high carbohydrate proportion of our food might be a further aggravating factor.

Gastro-intestinal and psychiatric disorders causing anorexia, nausea, and vomiting, are clear examples of conditioning; alcohol in place of other food causing anorexia and chronic gastritis and reducing thiamin intake, also provokes a change from a previously satisfactory diet to something like dry toast, highly seasoned food, coffee or spirits, which may lead again to any of the deficiency diseases.

Diets prescribed with prolonged restriction of certain essential food factors are occasionally responsible for deficiency states—e.g., in peptic ulcers, obesity, colitis, food allergy, and nephritis. Slimming diets are especially harmful, though their low calorie content gives some measure of protection for a limited time. Even well-planned reducing diets are usually short of B vitamins, and it is advisable to supplement them with brewer's yeast and vitamin A concentrate.

TABLE 1.—Factors Interfering with Ingestion

Anorexia:
Due to alcohol, operations, debilitating or infectious diseases, congestive heart failure, pregnancy, thiamin deficiency.
Gastro-intestinal disorders:
Gastro-enteritis, vomiting, peptic ulcer, gall-bladder disease, obstructive lesions of the gastro-intestinal tract.
Neuro-psychiatric disorders:
Psychosis, neurosis, migraine, anorexia nervosa, neurological disorders interfering with food intake.
Unsatisfactory denture, loss of teeth.
Therapeutic restriction of essential foods:
Peptic ulcer, obesity, nephritis, allergy, occasionally gall-bladder disease and diabetes.
Monotony and lack of variation in the diet.
Disproportion in the protein, fat, and carbohydrate ratio.

Interference with Absorption

Anatomical, chemical, and physiological changes (Beams *et al.*, 1941) may all interfere with the absorption from the intestinal tract. The reduction of the absorbing surface, hypermotility of the gastro-intestinal tract, and absorbants and lubricants introduced perorally may all be instrumental. In diarrhoeic conditions the reduction of the absorbing surface and

the hypermotility with the rapid passage are causal factors. The clinical importance of diarrhoea in producing pellagra, sprue, riboflavin deficiency, hypocalcaemia, and vitamin A and D deficiency is well known. In the sprue syndrome the hypermotility seems to be reduced by improvement of phosphorylation (Leitner, 1942), by an adequate supply of the B complex in the form of crude liver extract, or even quicker by synthetic folic acid (Spies *et al.*, 1946; Manson-Bahr and Clarke, 1946).

Achlorhydria may interfere with the absorption of ascorbic acid (Alt *et al.*, 1939) and of thiamin (Melnick *et al.*, 1941). In unexplained malnutrition, especially in patients over 40, achlorhydria should always be suspected.

Bile salts play an important part in the absorption of fat and of the fat-soluble vitamins, especially that of vitamin A (Brees and McCoord, 1939) and natural vitamin K (Snell, 1939). The habitual taking of liquid paraffin for bowel regulation also interferes with the absorption of vitamin A (Andersen, 1939) and vitamin K (Elliott *et al.*, 1940). Aluminium hydroxide and kaolin may absorb the water-soluble vitamins from the gut (Bicknell and Prescott, 1946). Resection, short-circuiting operations, and fistulas of the gastro-intestinal tract have long been known to produce macrocytic anaemia and the sprue syndrome (Bennett and Hardwick, 1940). Peripheral neuritis due to interference with absorption in cases of pyloric stenosis, dysphagia, cardiospasm, and neoplasms of the gastro-intestinal tract may respond to parenteral treatment with thiamin (Laurent and Sinclair, 1938).

TABLE II.—*Factors Interfering with Absorption*

Achlorhydria.
Vitamin deficiency (sprue syndrome).
Gastro-intestinal disorders:
Hypermotility, reduction of absorbing surfaces, oss of mucosal integrity (carcinoma of stomach, intestinal tuberculosis, gastro-intestinal fistulae).
Biliary disorders, especially obstructive jaundice.
Therapeutic measures:
Liquid paraffin, colloidal absorbents, gastro-intestinal resections, short-circuiting operations, severe catharsis.

Interference with Utilization

The evidence for this is mainly circumstantial, as direct experimental verification is extremely difficult. Provided that the intake is adequate, it is imperative to exclude interference with absorption, increased destruction and excretion, as well as abnormal requirements before defective utilization may be concluded. Carotene has to be converted into vitamin A; thiamin phosphorylated into cocarboxylase; nicotinic acid into coenzymes I and II, etc. These changes may occur in different tissues, but at present most evidence points to the liver as being the main organ for these processes (Moore, 1931; Sydenstricker, 1941), although it was recently suggested that carotene might be converted into vitamin A in the intestine (Glover *et al.*, 1947). In the case of liver dysfunction not only the conversion but also the storage and release of these substances is interfered with. In this way the body becomes dependent on the very variable daily intake, and as storage of the excess is also impaired a deficiency is bound to occur sooner or later.

Vitamin-A deficiency has been established in chronic liver diseases (Haig and Patek, 1942), obstructive jaundice (Stewart and Rourke, 1941), and hypothyroidism (Wohl and Feldman, 1939). Similarly in certain skin conditions, such as Darier's disease, Devergie's disease, and ichthyosis, in which low plasma vitamin-A values were repeatedly observed, impaired liver function could be demonstrated (Leitner, 1946a; Leitner and Moore, 1946). The low plasma vitamin-A levels found in patients with cancer of the gastro-intestinal tract have been attributed to failure in utilization due to hepatic dysfunction (Abels *et al.*, 1944) as in the various nutritional diseases in alcohol addicts (Lancet, 1941).

Factors interfering with utilization are: hepatic dysfunction (liver cirrhosis, chronic hepatitis, alcoholism); hypothyroidism, and malignant diseases of the gastro-intestinal tract.

Increased Body Requirements

The daily and adequate nutritional intake should cover the increased requirements. Under certain conditions, however, the requirements are increased far beyond the normal level, and these exceptions might be considered as follows. It is known that the basal metabolism

about 13% for each degree centigrade, strong emotion may also increase the metabolism considerably, while strenuous exercise or very hard work may even raise it to five to fifteen times above the basal level (Best and Taylor, 1943).

The influence of sunshine in the provocation of deficiency symptoms is well known. Its precipitating effect in pellagra ("mal di sole") is partly ascribed to its traumatic action (Smith and Ruffin, 1937) and partly to the excretion of the B vitamins in sweat (Cornbleet *et al.*, 1943).

A conditioned deficiency may be produced by thyroid, dinitrophenol, and fever therapy, which increases the whole metabolism, or by high carbohydrate diet, insulin-shock therapy, and parenteral administration of large amount of glucose, which increase the demand for coenzymes (Spies *et al.*, 1938). The water-soluble vitamin-B group, especially thiamin, may easily be washed out of the tissues and used up by repeated glucose infusions (e.g., after operations). The resulting "water-logging" (Sydenstricker, 1941) after excessive parenteral administration of glucose is a manifestation of thiamin deficiency.

Pregnancy and lactation have long been known to provoke symptoms of vitamin deficiency. Nixon *et al.* (1942), utilizing his material in Hong Kong and in this country, found besides pregnancy neuritis, already described in this country (Theobald, 1936), conditions allied to toxæmia and beriberi in undernourished pregnant women. It is not yet clear whether these symptoms are due only to increased requirements. Damage of the liver from pregnancy toxæmia may also lead to impaired liver function interfering with the utilization and storage of thiamin, choline, and other members of the vitamin-B group.

The importance of large doses of a single synthesized vitamin as a conditioning factor is still insufficiently recognized. Since Spies, Bean, and Ashe (1939) and Sydenstricker *et al.* (1940) first noticed that symptoms of thiamin and riboflavin deficiency became more pronounced in pellagrins after nicotinic acid treatment similar occurrences have been repeatedly recorded in clinical medicine. Lehmann and Nielsen (1939), Braendstrup (1940), and Salvesen (1940) described signs of pellagra after large parenteral doses of thiamin. Bichel and Meulengracht (1941) reported the development of pellagra after treatment with riboflavin; Leitner (1945) described signs of riboflavin deficiency after large parenteral doses of thiamin. Repeated attempts to produce imbalance of the vitamin-B factors experimentally have been unsuccessful, but Richards (1945) was able to induce fits in rats kept on pyridoxin-poor diet after large doses of thiamin, whilst the fits (characteristic of pyridoxin deficiency) could be entirely prevented if small doses of pyridoxin were given before the thiamin. Richards also suggested that one of the two types of thiamin toxicity described previously by Leitner (1943) which resembled thyroid overdosage might well be considered a vitamin deficiency induced by excess of the single vitamin.

Apart from the comparatively small number of verified descriptions of this syndrome, one encounters in hospital and private practice many partly abortive cases which often appear after repeated parenteral doses of one single vitamin—mainly thiamin.

A woman admitted to hospital with menopausal arthritis and gross adiposity was given a routine slimming diet, mersalyl, and thyroid. After having lost about 1 st. (6.35 kg.) in weight she still complained of shortness of breath; there were no signs of organic heart disease, and it was suggested that the shortness of breath was due to thiamin deficiency. Daily parenteral injections of 25 mg. of thiamin improved the breathlessness within five days, but painful cracks developed at the angles of the mouth, followed by crust formation and cheilosis.

Leitner (1946b, 1947a, 1947b) emphasized again that subclinical latent deficiencies within the vitamin-B group may often become manifest after energetic treatment of the obvious deficiency. Farrar (1947) found that administration of large doses of thiamin in inadequately nourished cases of pernicious anaemia aggravated the glossitis and caused diarrhoea and pellagrous dermatitis, but no pellagra-provoking effect of thiamin could be observed in the same patients when adequate diet had been given. He also found that haematological relapse appeared quicker when nicotinic acid was administered after stopping liver treatment. Davidson and Girdwood (1948) observed in two cases of pernicious anaemia and three cases of sprue the appearance, during treatment with folic acid, of

MAY 15, 1948

EARLY VITAMIN-DEFICIENCY STATES

vitamin-B complex deficiency, consisting mainly of peripheral neuritis, cord involvement, angular stomatitis, cheilosis, and pellagrous dermatitis with depression. Whilst administration of purified vitamins was of little avail, potent liver extract always brought about an improvement. As the liver extract contains only traces of the vitamin-B complex, produced the most dramatic effect on a wide variety of vitamin-deficiency symptoms. Davidson and Girdwood suggest that liver extract may contain a factor which liberates members of the vitamin B complex from their inactive form or facilitates their absorption or utilization. Leitner (1948b) subsequently put forward again the explanation that large doses of one purified vitamin (i.e., one single enzyme system) may easily upset the balance in deficiency states or may exert an inhibitory effect on other enzyme groups which at that particular time are present in abnormally low amount. The well-balanced multiple enzyme systems present in potent liver extracts may restore the disturbed equilibrium without containing large doses of any of the known purified vitamins.

TABLE III.—Factors Increasing Body Requirements

Increased activity:	Increased physical effort	Increased demands
Sirens and prolonged physical effort	Excessive winds	
Certain environmental influences		
Certain manufacturing processes and industries		
Certain glare (snow)		
Fever		
Pregnancy and lactation		
Hyperthyroidism		
Therapeutic measures		
Thyroid, alpha-dinitrophenol, parenteral dextrose or excessive		
continuous fluid intake as in urinary infections, high carbohydrate		
diets, fever therapy		
		large doses of a single pure vitamin

Increased Excretion
Increased excretion of vitamins may secondarily lead to malnutrition, but there are very few substantiated observations to this effect. Lactation polyuria or forced water-intake (Cowgill *et al.*, 1930) may cause increased excretion of vitamins (e.g., in urinary infections, sulphonamide treatment). The occasional observation of a mild gestational polyneuropathy with rapid development of symptoms and signs during the first few weeks of lactation might be an example of increased excretion. Excessive perspiration in the Tropics might condition a deficiency of the water-soluble B vitamins, as some of them appear in sweat in a considerable concentration after heavy physical exercise (Cornbleet *et al.*, 1943).
The main factors that increase excretion of vitamins are: (1) polyuria (diabetes mellitus, after excessive intake like urinary infections, sulphonamide therapy); (2) lactation; (3) excessive perspiration.

Increased Destruction
Induced vitamin deficiency in animals has long been known. Generalized erythematous scaly dermatitis with pruritus, arrest of growth, spastic gait, and abnormal posture could be produced by feeding raw egg-white in animals (Boas, 1927) and man (Sydenstricker *et al.*, 1942). The cause of this syndrome is a biotin deficiency. The glycoprotein (avidin) contained in the raw egg-white forms a complex with biotin. Cooked egg-white, and this complex cannot be broken down. Another biotin, and this complex does not inactivate biotin. And death, white, on the other hand, does not inactivate biotin. A severe deficiency is chaste paralysis in silver foxes fed on raw fish. It consists of anorexia, hyperaesthesia, ataxia, and death with cerebral lesions similar to Wernicke's encephalopathy, and it is due to thiamin destruction caused by injection of vitamin B₁ (Melnick *et al.*, 1942) or by cooking the fish. Although both conditions are very probably not due to simple destruction of the vitamin, it is perhaps pertinent to mention them here—"antivitamins," "inhibitors" (Woolley, 1944).
Factors leading to increased destruction of vitamins are: (1) achlorhydria; (2) alkalis, sulphonamides; (3) toxic doses with lead? arsenicals? gold?

Achlorhydria seems to interfere with the assimilation of ascorbic acid. Alt *et al.* (1939) have shown 65% destruction of ascorbic acid in three hours at a pH of 7.95, and Melnick *et al.* (1941) found that thiamin is stable in acid gastric juice (pH 1.5 to 8) during an incubation of 16 hours, but if antacids were added thiamin was completely destroyed. Bile and pancreatic juice also destroyed a considerable part of thiamin.

It has been claimed that vitamins, especially vitamin C, are often destroyed owing to their "detoxifying" actions—e.g., by arsenicals, gold, lead, sulphonamides, barbiturates, T.N.T., etc.—but the evidence is conflicting (Bicknell and Prescott, 1946).

The discovery of biosynthesis of vitamins by the intestinal flora focused some attention on sulphonamide therapy. It was known for some time that sulphonamides reduced the therapeutic action of nicotinic acid. Whilst there could be competition for the same enzyme system (Wood, 1929) between sulphapyridine and nicotinic acid, the explanation did not hold good for sulphonamides not containing the pyridine ring. Later it could be shown in man that, after giving sulphaguanidine or sulphasuxidine, the vitamin biosynthesis—e.g., that of thiamin (Najjar and Holt, 1943), riboflavin (Najjar *et al.*, 1944), nicotinic acid (Ellinger *et al.*, 1944)—in the intestines was substantially reduced or perhaps completely inhibited. As the extent of the biosynthesis is at present unknown the loss of this function may be considered from a practical point of view equivalent to destruction.

Diagnosis

Diagnosis of early vitamin-deficiency states is exceedingly difficult. The deficiency should be diagnosed at a time when symptoms have not yet been developed into the textbook description of deficiency disease in the latter case the patient would be severely ill. The early symptoms are often non-specific, and laboratory methods are usually of little help at this stage, and to recognize the condition reliance has to be placed on the patient's dietary history. Complete reliance has to be placed on the patient's physical examination on indefinite symptoms and signs found on physical examination, and on a balanced clinical judgment. Complete nutritional failure is a rare condition in this country, but different degrees of deficiency state with a host of vague symptoms are frequent enough to warrant serious concern. In the earlier stages of vitamin research there was an inclination to attribute definite symptoms to a particular vitamin, but clinical experience has taught us that with greater frequency it takes the form of borderline states of ill-health owing to multiple deficiencies, often with vague symptoms which might easily be attributed to other causes.

Personal and Dietary History

The U.S. Public Health Service states that nutritional diseases constitute their greatest medical problem, not from a point of view of death but from that of disability and economic loss (Wohl, 1945). The fact that no similar statement has been made by public health authorities in this country does not by any means imply that the problem is non-existent here.

Grossly inadequate diet can be recognized without difficulty. Particular consideration should be given to patients on any special diet—e.g., those with obesity, peptic ulcer, dyspepsia, diabetes, etc. Detailed attention should be paid to dietary history in cases of psychoneurosis.

Clinical Examination

As manifold deficiency symptoms usually occur simultaneously, a wide variety of vague and interwoven symptoms are met with. The earliest symptoms consist of such general complaints as anorexia, fatigue, loss of weight, restlessness, irritability, paraesthesias, cramp in the muscles, burning of the eyes, photophobia, dimness of vision, impairment of memory, etc. These vague symptoms may be caused by different deficiencies, and they become pronounced with advancing disease. In a vitamin-A deficiency clinical signs are detectable only when the process is moderately advanced. Perhaps the earliest change is xerosis conjunctivae, which can be observed if the eyelid of the patient is kept open for a few minutes; the lustre is lost owing to the rapid drying of the conjunctival epithelium, due to metaplasia and thickening of the conjunctival epithelium, which reduces the secretion. It may be the earliest sign of vitamin-A deficiency. Like night-blindness—another symptom of vitamin-A deficiency—it is not specific, and both might have several other aetiological causes. Xerosis conjunctivae may later develop into Bitot's spots, which may or may not be

associated with night-blindness. Burning of the eyes, lacrimation, photophobia, and discharge are further early eye symptoms. More advanced changes of vitamin-A deficiency are to be seen in the skin, which becomes dry, scaly, and horny, with the typical papules around the follicles. Late stages of vitamin-A deficiency are connected with more pronounced damage of epithelial structures, mainly of the mucous membranes.

In a survey of 195 hospital and private patients with complaints not expected to interfere with the vitamin-A level, normal blood carotene and vitamin-A values were found (Leitner and Moore, 1948a). No signs of vitamin-A deficiency could be detected in any of these cases clinically. We found, however, low vitamin-A values in certain rare skin diseases (Leitner and Moore, 1946, 1948b) with characteristic skin lesions (Leitner, 1947c).

The early changes of vitamin-B deficiency are the most frequently met with in practice. It has been mentioned that the various members of the vitamin-B complex are grouped together more by virtue of their association in nature than by any structural similarity. Owing to their close association deficiency symptoms of the various members of the group overlap even more than would at first be expected.

The earliest signs of thiamin deficiency are generally ill-defined, and they are due most probably to deficiency of the entire B complex. The prodromal period may be described as a period of ill-health lasting for a long time. As thiamin is mainly concerned with metabolism of the nervous tissue, early deficiency symptoms chiefly connected with the abnormal function of the nervous tissues, such as anorexia, fatigue, irritability, dizziness, apprehension, etc., might be expected to form part of the clinical picture. But these symptoms are absolutely unspecific, like many of the early symptoms of other vitamin deficiencies, and the laboratory methods available are not sensitive enough to determine their origin. It may be argued that dementia is the earliest symptom of many of the slowly developing pathological conditions, the specific symptoms and signs being much later. It has, indeed, been my experience that many of the symptoms and signs follow if the symptoms mentioned remain untreated, and therapeutic tests corroborate this assumption. Though these early symptoms attributed to deficiency are often encountered, properly controlled large-scale studies have never been carried out.

Signs of the loss of weight, inability to concentrate, and the present digestive disturbances, intermittent pain and numbness, soreness at the corners of the mouth, and burning of the eyes with visual disturbances, headache, depression, and depression are early signs attributed to deficiency (Schrell and Butler, 1938) differentiated by the following experiments the well-known symptoms which later are found in hyporiboflavinosis (Stannus, 1944): paleness of the lips, followed by maceration and bilateral superolateral lesions at the angles (angular stomatitis); the lips become chapped, cracked, and crusted with transverse fissures. The tongue is clean, the papillae are normal, but there is patchy denudation and congestion of the capillary loops leading to magenta colour in contrast to the atrophic, often painful scarlet-red tongue in pellagra. A dry, scaly, somewhat "branny" desquamation on an erythematous base on the alae nasi, on the naso-labial folds, eyelids, and occasionally the hands, vulva, and perineum, are other early signs (Schrell and Butler, 1938). Ocular disturbances (Spitz, Viter and Ashe, 1939) such as conjunctivitis, burning, photophobia, pruritus, sensation of sand, and corneal vascularization leading later to punctate opacities are regarded by many investigators as the earliest signs of hyporiboflavinosis (Schrell and Butler, 1938).

Nicotinic acid deficiency is also introduced by a long period of ill-health, a "development time" characterized by loss of weight and weight disturbances of the alimentary tract, general weakness, fatigue, irritability, insomnia, depression, inability to concentrate, vertigo, numbness, palpitation, and a general sense of loss of memory, and confusion. At this stage, if no other signs are present and the diagnosis of deficiency is not supported by laboratory methods, the diagnosis of deficiency is easily made. The characteristic skin changes and dermal lesions appear

much later. Hyperaesthesia of the tongue may precede the swelling, redness, and indentation caused by the teeth. Desquamation of the superficial layer causes a scarlet-red, dry, smooth, beefy tongue which is often painful. Secondary infection with monilia and Vincent's organisms over the fissures and aphthous ulcers occurs frequently, and the inflammatory process often extends to the neighbouring mucous membranes. The associated angular stomatitis and cheilosis might respond to riboflavin treatment. (Angular stomatitis may also be caused by ill-fitting dentures, dribbling, chewing-gum, and lipstick.) The characteristic skin lesions may sometimes be missed (pellagra sine pellagra). They are more often than not symmetrical, and may be precipitated by sunlight or other irritation. Hands, face, neck, knees, feet, and perineal regions are favourite places, but the sunburn-like, erythematous, pigmented, often hyperkeratotic, and distinctly demarcated lesions may appear anywhere. Mental symptoms such as emotional instability, depression, and confusion may be precipitated suddenly (Gottlieb, 1944), or within a few days in persons on deficient diet.

A woman, aged 64, who lived for 10 years on a restricted diet developed pulmonary tuberculosis. She was admitted to a sanatorium and improved greatly on a full diet. After eight months' sanatorium treatment she suddenly developed diarrhoea, accompanied by anorexia. Within a few days changes occurred in the oral mucous membrane, followed by depression and confusion, and the skin and eye changes characteristic of pellagra were fully developed (Rinington and Leitner, 1945).

It would exceed the scope of this paper to discuss the possible relationship of macrocytic and microcytic anaemias to vitamin and nutritional deficiencies. It is perhaps sufficient to refer to the results achieved with another B vitamin—folic acid—in macrocytic anaemia, in the sprue syndrome, and in allied conditions.

Early vitamin-C deficiency is another widespread condition. Owing to the scarcity of citrus and other fruit and fresh vegetables for many years, congested, swollen, purple-red, easily bleeding gums occur comparatively often. I have also seen florid scurvy on five occasions during recent years, mainly in old single men who normally cooked only once a week for themselves and lived predominantly on warmed-up, overcooked meals. Fatigue, weakness, and anaemia are often early unspecific signs of vitamin-C deficiency, together with localized follicular keratosis. Petechial haemorrhages are usually moderately advanced signs, and although increased capillary fragility is more and more attributed to vitamin-P deficiency (Scarborough, 1940), the two substances appear to be associated in nature.

Laboratory Tests

These are of little help in early vitamin-deficiency states. Urinalysis is usually normal. The blood picture may or may not show a moderate microcytic or normocytic anaemia. Blood sedimentation rate, total serum proteins, and albumin globulin ratio are usually within normal limits. The fractional test meal often shows an achlorhydria, but this is neither pathognomonic nor characteristic. It is said that oesophagoscopy and gastroscopy usually reveal the same changes as are found in the buccal cavity. The "deficiency pattern" of the small intestine found on x-ray examination with abnormal segmentation, pooling, disappearance of herringbone structure, obliteration and coarsening of the mucosal folds (Golden, 1941), although not always characteristic, may offer some indication of a B-complex deficiency.

During the last few years exact laboratory tests have been worked out for the determination of a given vitamin in the blood; saturation and excretion tests were also introduced. The assessment of the vitamin status, especially in the case of early deficiency, is, however, not simple. While the results of saturation tests as shown recently by Ellinger and Hardwick (1947) for nicotinamide may be affected by unknown mechanisms, low vitamin values in the blood and urine may, on the other hand, be found without depletion of stores in the organs; these findings are at times singularly uncharacteristic in cases of early deficiencies, and can be used only with great caution in the assessment of physiological deficiency. Moreover, it is essential that the laboratory data should be carefully correlated with the clinical findings. Within these limits, however, it is obvious that exact laboratory tests can

substantially contribute to the detection of subclinical deficiency states. For vitamin A the chemical estimation of the vitamin in plasma and the estimation of the dark-adaptation, for thiamin and riboflavin the determination of the excretion of vitamin B₂ and B₆, are the routine laboratory tests. Saturation tests are used for the assessment of nicotinic acid and ascorbic acid; some also rely on the vitamin-C estimation in the white cell layer, on the determination of capillary fragility, and on x-ray changes in the bones. The great difficulty with these procedures is that they nearly always require specialized laboratory technique.

Differential Diagnosis of Early Symptoms

As naturally occurring deficiency is always multiple, the associated symptoms are, especially in the early stages, often interwoven, and this makes the diagnosis of a deficiency of a specific chemical substance most difficult. Vague, ill-defined, waxing and waning complaints, prominent among them being fatigue, weakness, loss of appetite, loss of initiative, irritability, personality changes—in fact, all the common symptoms of neurasthenia—are frequently encountered. The patients are neurasthenics, indeed, and it is often difficult to separate these two conditions, particularly as neurasthenics are liable to eat an inadequate diet. Weir Mitchell long ago established that some neurasthenics benefited by a properly balanced forced diet combined with rest; and after careful study of the modern version of Weir Mitchell's method—the modified insulin treatment in neurotics (Sargent and Slater, 1944)—one wonders whether seclusion and reassurance or proper food are more important for their cure.

TABLE IV.—Symptoms described as manifestations of Early Vitamin Deficiency (after Cayer, 1946)

Fatigue*	Paraesthesia*	Depression*	Weakness*
Insomnia*	Palpitation*	Abnormal diet*	Lassitude*
Anorexia*	Nervousness*	Muscular weakness*	Muscle pain*
Veniso*	Irritability*	Backache*	Lack of concentration*
Headache*	Dyspepsia*	Apprehension*	Apathy*
			Confusion*
			Decreased output of work*

*Symptoms given as symptoms of neurasthenia in the textbooks of medicine

Table IV may facilitate the appreciation of the overlapping between symptoms of early vitamin-deficiency states and neurasthenia (Cayer, 1946). This overlapping unfortunately led to the indiscriminate use of vitamin preparations all over the world. All evidence, however, shows that administration of vitamins without underlying deficiencies does nothing to improve the patient.

The difficulty in the assessment of early deficiency states warrants the occasional administration of vitamins as a therapeutic test. If the quick disappearance of symptoms is followed by general well-being the suspected diagnosis might have been right. Great care, however, has to be exercised, as slight improvement often follows any therapeutic trial.

Treatment

The underlying principle of the treatment of early vitamin-deficiency states is to deal with the conditioning factors and to supplement the tissue deficiencies. The degree of depletion of the various food factors varies in different patients, and, whilst often only one deficiency symptom predominates in the clinical picture, it has to be borne in mind that other deficiencies are also likely to be present. Food contains many still unknown factors certainly necessary for proper nutrition, and these are not present in synthesized vitamin preparations. The basis of treatment consists accordingly in securing an adequate diet.

It is quite evident that provision of the average daily requirements is not sufficient to make up for past losses. Although some of the patients showing early vitamin deficiencies may appear obese and overnourished, an investigation of their food intake will show that they have an unbalanced diet. The intake in these cases ought to be at least 3,500 calories, containing 120–130 g. of proteins (calculated for a person of 11 st.—70 kg.). This diet cannot be given easily to patients in this country at present:

our rations, even with additional foods for invalids, cannot provide either the necessary calories or the suggested protein intake. It is to be hoped, however, that the world food situation will soon enable the food policy of this country to be altered, at least for those who are in special need. Table V indicates the foods rich in different vitamins.

TABLE V.—Food Rich in Vitamins

Vitamin A	Thiamin	Riboflavin	Nicotinic Acid	Ascorbic Acid
Butter	Wholemeal	Wholemeal	Bran	Blackcurrant
Milk	Quatmeal	Bran	Peasants	Rose-hip
Cheese	Bran	Nuts	Chicken	Lemon
Eggs	Peas	Beans	Pork	Orange
Carrots	Beans	Peas	Beef	Lime
Broccoli	Lentils	Broccoli	Liver	Grapefruit
Lettuce	Parsnip	Endive	Kidney	Strawberries
Spinach	Nuts	Spinach	Heart	Tomatoes
Tomatoes	Milk	Mushrooms	Meat extracts	Green Peppers
Liver	Eggs	Milk	Salmon	Red pepper
Eel	Fish-roe	Cheese	Mackerel	(Capsaicin)
Carp	Pork	Eggs	Brewer's yeast	Potatoes
Fish-liver oils	Veal	Fish-roe		Cabbage
	Beef	Kidney		Spinach
	Brewer's yeast	Liver		Cauliflower
		Meat extracts		Turnips
		Brewer's yeast		Fenugreek
				Sun-dried
				Dandelion

In addition to a rich and well-balanced diet, vitamins should be administered in deficiency states. Parenteral administration of vitamins should be restricted to emergencies and to those cases in which there is obvious interference with absorption. As indicated earlier, large doses of parenterally given pure vitamins, especially those of the B group, may provoke a serious imbalance, and even if there is a deficiency of the administered vitamin they sometimes cause more harm than good. This point should be specially stressed, as there are indications that latent deficiencies without obvious clinical signs and symptoms are much more widespread than is realized. In early vitamin deficiencies something like five to ten times the daily minimal requirement should be given—e.g., thiamin and riboflavin 10–15 mg., nicotinamide 100–200 mg., ascorbic acid 150–300 mg., in divided doses three times a day. Fat-soluble vitamins should be given in larger doses, and my practice is to give 50,000 to 100,000 i.u. of vitamin A daily. As vitamin-A deficiency is often connected with disturbance of liver function, simultaneous parenteral application of liver extract seems, in my experience, to reduce the time needed for correction of the deficiency (Hoagland, 1945). Vitamins D and K are outside the scope of this paper, and no therapeutic suggestion is therefore given for deficiency of these.

In cases of deficiency of one of the vitamins of the B group it is advisable to give, instead of the most obviously lacking factor, a mixture of thiamin, riboflavin, nicotinamide, and possibly folic acid, together with brewer's yeast, 1–1½ oz. (28–42 g.), or liquid liver extract, 1 oz. (28 ml.), daily. Injection of the less refined liver extracts may also be tried. Symptoms usually begin to improve after two to four weeks, but as the depletion may be of long standing it is advisable to continue giving smaller doses for a longer period, particularly as dietary treatment alone in this country is bound to be ineffective for some time to come.

Summary

Deficiency states may be caused solely by the failure to ingest an adequate diet, or may be conditioned by factors which interfere with ingestion, absorption, and utilization, or by conditions which increase the requirements for vitamins and their excretion or destruction. The physiological and pathological aspects, and the therapeutic measures, that may result in a conditioned deficiency state, are briefly discussed.

The clinical diagnosis of early deficiency states is exceedingly difficult, as the deficiencies tend to be multiple and the symptoms in many instances are non-specific. Physical signs are often

in part, and laboratory findings may not be characteristic in the early stages. Diagnosis should not be made on the basis of symptoms alone; careful evaluation of the dietary history, symptoms and signs, the available laboratory data, and response to specific therapy may help to establish the cause.

Not only a number of diseases but also some of the therapeutic measures used to combat them may precipitate a deficiency state, and the imbalance of vitamin-B factors is particularly stressed. The treatment of early vitamin-deficiency state is in every case an individual medical problem requiring exact diagnosis and properly planned therapeutic measures.

I am greatly indebted to Drs. F. J. Bentley, W. I. Card, T. Moore, and Prof. H. A. Krebs for much help, advice, and valuable criticism.

THE TREATMENT OF NEUROSYPHILIS WITH PENICILLIN*

BY

JAMES PURDON MARTIN, M.D., F.R.C.P.

Physician to the National Hospital, Queen Square;
Neurologist to the British Postgraduate Medical School

The powers of penicillin have excited the whole world but penicillin was introduced as an antibacterial remedy and it was not to be expected that it would be potent against the protozoal infection of syphilis. Moreover, it was soon discovered that penicillin given intramuscularly did not find its way into the cerebrospinal fluid; it did not, it was said, pass the blood-brain barrier; and so it was inherently improbable that it would have much effect on syphilis of the nervous system. We knew also that nowhere did the spirochaete entrench itself more strongly than in the brain; we knew that general paralysis especially was a hard nut to crack. It was therefore right and natural that the first rumours that penicillin was in some degree effective in cases of neurosyphilis, and even in cases of general paralysis, should be received with a certain amount of incredulity; and this attitude is apparent in most of the reports on the trials of penicillin in neurosyphilis, because nearly all observers, finding some clinical improvement but little immediate change in the cerebrospinal fluid and blood, have gone on to treat their patients with malaria. General paralysis is a progressive and inexorable disease that allows no temporizing, and one must have good reason for withholding the well-tried standard, if desperate and often inadequate, remedy.

My own attitude at the beginning was the same. Early in 1945 some penicillin became available for civilian hospital use in diseases for which it was known to be appropriate, and just at that time I had admitted to the National Hospital under my care a man of 50 suffering from taboparesis.

This patient was euphoric and fatuous, and had recently lost his position as a secretary-accountant because of his inability to carry out his duties. He was pursuing allotment gardening in a hypomanic way, and had undertaken several allotments though he was a small weak man. At home he was restless, irritable, obstinate, and sometimes tearful. He had some tremor of his lips and tongue and a tremulous dysarthria, and also some tremor of his hands. His pupils were inactive to light, his knee-jerks and ankle-jerks were absent, and his plantar reflexes were weakly extensor. His cerebrospinal fluid showed typical parietic characteristics and his blood Wassermann reaction was strongly positive. I decided to try the effect of penicillin, and we were able to obtain the required amount. The reports which had come from America had at first suggested that over a million units might be necessary, but by the time treatment was started on this patient it was being said that even two million units were required, and he was given a course

*A paper read to the Society for the Study of Venereal Diseases on Jan. 24 (abbreviated).

of two million units in injections of 20,000 units every three hours. When the course was finished he had certainly made some clinical improvement. He was less restless, a little less expansive, and his concentration and memory were better. Physically he was less tremulous, but the other physical signs were of course unchanged. To our disappointment his cerebrospinal fluid, examined ten days after the completion of his course of penicillin, showed practically no change.

The Americans had had a long start of us, and the few reports which were then available indicated that penicillin was inadequate, and that it was necessary to use malaria as well. Faced with the lack of serological improvement in my patient and with this information from America, I thought it obviously the appropriate course to proceed with malarial therapy and this was done without waste of time. I did nevertheless say, being impressed with the clinical improvement, that it would be a pity to cure the patient with penicillin and then, for the sake of confirming the cure, to kill him with malaria. As it turned out, this very nearly happened. At the time of his fifth rigor the patient passed into a semicomatose state with low muttering delirium, and the malaria was hurriedly arrested. Nevertheless he remained in a condition first of semicoma and muttering, and later, for nearly a fortnight, in a condition of profound dementia with lapses into delirium and it seemed as if he was unlikely to survive. However, he gradually came round, and in the end made a very good recovery, although I do not think his mental state has ever been quite so good as it was before the malaria started.

This was by no means my first *fortis* triumph with malaria, but it was a new lesson. Meanwhile Dr Carmichael had started one of his patients on penicillin—case of Frank G.P.I. in a man of 58—and invited me to follow the case with him. This man, when a course of three million units was finished, also showed clinical improvement, but his cerebrospinal fluid still had "paretic" abnormalities, and his blood Wassermann reaction was still strongly positive. Nevertheless we decided that we should treat the patient and not the cerebrospinal fluid, and clinically we saw no call for immediate further treatment, and certainly no justification for submitting him to the dangers from which the first patient had so narrowly escaped. After a short period of observation in the hospital, during which he continued to improve, he was allowed to go home. His improvement continued and after a few months he was very much better clinically. Since then I have treated well over 30 cases and none of them has had malaria, so that the following series of cases were treated either with penicillin alone or with penicillin supplemented only by the usual chemicals.

Present Series

The series consists of 24 cases which I had treated at the National Hospital, Queen Square, before the end of September last. The number is small compared with some of the American series, but this will not surprise those who are aware of the extent of the decline of neurosyphilis in this country (an interesting subject in itself which I hope to discuss at another time). Even in the American reports the number of cases described as treated by penicillin alone is not so very large, most of the big series consisting of cases treated by combined methods.

The cases hitherto published in England are few. Smith (1947) reported seven cases of general paralysis treated by penicillin alone and observed for periods up to 13 months. Lescher and Richards (1947) described 10 cases of neurosyphilis of different types treated with penicillin alone and other cases treated by combined methods. Nicol and Whelan (1947) have referred to the immediate effects in 14 cases treated with penicillin alone, and a larger number with a combined method.

My series is a mixed bag of all varieties of neurosyphilis. There were eight patients who presented mental symptoms, and they all had "paretic" spinal fluids: one other patient

whose presenting symptom was hemiparesis, due evidently to a vascular lesion, also had a "paretic" fluid. Five patients were typical cases of tabes and two others were predominantly cases of optic atrophy, while nine patients were instances of different varieties of meningo-vascular syphilis.

Group 1, Dementia Paralytica.—Under this heading I include all cases with dementia and "paretic" changes in the cerebrospinal fluid. The group consists of eight cases—Nos. 1, 3, 7, 9, 14, 18, 20, 21, in chronological order—all of which have been followed up for at least six months and five of them for more than 12 months. The patient in Case 1 works two allotments himself and acts as secretary for the local allotment holders; in Case 3 the patient has for a long time been back at his former work as a timekeeper. Case 7 was one of paresis in a woman of 60, who has shown great clinical improvement in the 20 months that have elapsed since her first treatment; whereas before her treatment she had to be cared for at home, she is now able to do her own housework and her shopping. Case 9 was one of paresis in a woman of 42; Case 14 was one of congenital infection in a woman of 27; in Case 20 the patient was a man of 59 who had received fever treatment by means of "sulfoxon" in 1935; in Case 21 the dominant clinical features were tabetic and the mental symptoms were slight. In all these cases the reports concerned have made clinical improvement and all are improving. The changes in the cerebrospinal fluids and fluids are shown in the Table. It will be observed that all the fluids have

remains normal except for the persistence of Lange (colloidal gold) curves in some cases and the presence of six cells at the last examination in Case 9.

Group 2, Tabes.—Of the five cases in this group—Nos. 6, 8, 10, 15, 19—three had received previous treatment. No. 19 has been lost sight of. None of the patients concerned had a very active syphilitic cerebrospinal fluid, and their fluids and blood have become normal with relative ease. Tabes being a chronic degenerative disease, not much positive clinical improvement can be expected, but the patients are better subjectively and their lightning pains are diminished. From the nature of the disease it will take many years to determine whether or not it is arrested.

Group 3, Optic Atrophy.—Two patients—Nos. 5 and 11—presented with optic atrophy. The greatest interest attaches to the first of these, a man who when first seen was blind in his right eye and complaining of diminishing vision in the left. Both disks were paper-white, and there seemed little chance of saving any sight. With particular precautions at the start and preliminary iodide and mercury, he was given five million units of penicillin, and excision of the stellate sympathetic ganglion was performed on the left side with the purpose of increasing the blood supply to the left optic nerve. No further diminution of sight was observed, and in the course of some months his acuity of vision in the left eye, which was at first 6/12, recovered to 6/9 and later to 6/6, and at present it is a little better than 6/6. The visual field has remained full. In the other eye, too, there was a little recovery of sight, which enables him to see hand movements in a part of the field. I have seen improvement of vision before in cases of optic atrophy followed subsequently by deterioration, and therefore cannot be quite confident about the outlook in this case; but it is now 2½ years since the first treatment, so that one can be hopeful. Nevertheless it is evident that in this case penicillin had an effective and prompt action. Case 11 is also noteworthy because it is the only one in the series in which symptoms continued to progress after a course of penicillin. The patient came under observation again after eight months and was given a second course of penicillin and also mercurial direction and in the succeeding eight months there has been no further deterioration of his sight.

Group 4, Vascular Syphilis.—Of the nine cases of vascular syphilis, three—Nos. 4, 16, and 17—presented with the following symptoms. Case 16 had generalized vascular disease with high blood pressure, a type of case in which little improvement can be expected. Case 17 had cerebral syphilis in her cerebrospinal fluid which are shown to be normal. Clinically and serologically she has improved. Of the remaining patients in this group the first two had subacute spinal syphilis, and these have shown moderate improvement. A young man with an unusual case of disease has also improved moderately. The other three were women with cerebral syphilis, two of whom had cerebral abscess, and all three of these patients have improved markedly after treatment.

Results in General

Reviewing these 24 cases, we may consider the apparent effects of the treatment in more general terms—the clinical effects, the effects on the cerebrospinal fluid, and the effects on the blood.

Clinical Effects. In most cases it is evident that the progress of the symptoms has been arrested; we may exclude from consideration in this respect the cases of tabes and the cases which have been lost sight of, and we are then left with 15 cases in which clinical progress can be assessed. In Case 11 visual impairment continued to progress after a course of treatment with penicillin was given, but in all the other cases the progress of symptoms has been arrested. In 12 of the 15 of the first course of treatment, and in nearly all of the 15 the patient has made positive recovery. Arrest of symptoms is all that can be expected clinically in the treatment of the disease, and the most effective treatment, and it is not possible to judge the effectiveness of treatment. Any positive effect is due to the arrest of the disease, and depends on the state of the

nervous tissue after the disease process has been stopped and its degree is not a measure of the effectiveness of the treatment. Whether the arrest of the clinical progress of the disease will be permanent it is impossible yet to say but as yet there have been no relapses and no deaths so far as I know.

Effects on the Cerebrospinal Fluid.—The effects on the C.S.F. and blood form the best criterion of the probable permanence of the arrest of the disease and of its eradication. In most instances the Wassermann reaction in the cerebrospinal fluid has become negative in about a year. It is not known when it became negative in Case 1, but it was found negative at the end of two years. The number of cells in the fluid usually becomes normal quickly and has always been within normal limits by the end of two months. The total protein content becomes normal more slowly, and frequently shows an increase immediately after treatment, which may last for one or two months. This is probably to be regarded as an indication of the reaction that has gone on in the tissues, and particularly in the cerebrum, and it is in keeping with what occurs in various other diseases. The tests for excess globulin usually become normal about the same time as the total protein. The colloidal gold reaction shows the most persistent of the changes in the cerebrospinal fluid, and in Cases 1 and 14 it is still of the paretic type after 30 and 12 months respectively when all other features of the fluid are approximately normal. As is well known, this also happens after malarial treatment, and the significance of this persistence is difficult to determine. In most instances, if the fluid is otherwise inactive, the reaction dies out in the course of some years, and it seems unlikely that an active colloidal gold reaction is to be regarded as any sign of activity of the disease. With the exception of the colloidal gold reactions, and occasionally of the total protein, all the cerebrospinal fluids in my series have returned to a normal state within about 12 months. The sequence of changes in the cerebrospinal fluid after penicillin therapy is thus exactly the same as that which follows successful treatment with malaria, and we may recall Dattner's insistence that a fluid which has become negative after malaria never becomes positive again.

Effects on the Blood.—It seemed at first that penicillin did not have much influence on the Wassermann reaction of the blood, but as time has gone on the reaction in the blood has become negative in a number of patients who have had no treatment except penicillin, and in some other patients it now shows a decided weakening. In cases in which N.A.B. and bismuth were given in addition the state of the blood is no better than in the others. In general the blood reactions in the series as a whole seem now as good as would have been obtained by any other method of treatment, but the delay in the correction of the blood Wassermann reaction after that of the cerebrospinal fluid has become normal is difficult to understand. A similar delay is known to occur after malarial treatment, but after penicillin it is more striking, possibly because other changes occur more quickly than after malaria.

The combined effects of the treatment on the clinical state and on the states of the cerebrospinal fluid and blood all indicate that treatment with penicillin is effective in arresting and exterminating the disease, and provide good grounds for expectation that the results will be permanent.

Dosage and Method of Administration

In all cases penicillin has been given by the intramuscular route only. Sodium penicillin was used for most of the cases, and in recent times the crystalline form whenever obtainable. We also made a trial of the beeswax preparation, but my house-physician at the time found some difficulty in working it, and it was abandoned.

TREATMENT OF NEUROSYPHILIS WITH PENICILLIN

In the early days the total amount given in each course was two million Oxford units (2M). This was soon increased to 3M, and then 4M; and for the last two years the course has been standardized at five million units (5M).

For the first day the doses are small, but thereafter half a million units are given every three hours, making nearly half a million units daily, and this rate of administration is continued until a total of approximately five million units has been reached. During the first day, as a precaution against Jarisch-Herxheimer reactions, much smaller doses are given. These may be either of the order of 15,000 units three times in the course of the day, or, as recently, 10,000 units hourly, with orders to stop administration if the patient seems upset or makes any complaint. No untoward reactions of any kind have been seen.

As will be seen, several of my patients have had repeated courses of penicillin. In the early days we had not appreciated the importance of time as a factor in the improvement of the cerebrospinal fluid and blood. We were not sure enough of our effects, and, dealing with such inexcusable conditions as paresis and optic atrophy, we could not afford to take any additional risks. One patient with dementia paralytica had three courses within eight months; another with optic atrophy three courses in 12 months. In the light of subsequent experience such intensity of treatment seems lavish and unnecessary. It is true that the results were very good in both cases, but probably not enough time was given for the full effects of the first course to show themselves, and the same results might now be obtained with more economy of treatment. Gammon, Stokes, *et al* (1946) suggest that the right time for repetition of the course is after four months, but my experience leads me to think that at that time the whole influence of the first course is not yet apparent either clinically or in the cerebrospinal fluid and blood, and if the clinical condition is satisfactory longer intervals may be allowed.

In several of my cases the cerebrospinal fluid has been examined for evidence of the presence of penicillin, but in no instance has it shown any inhibiting effect on the standard test cultures.

Adjuncts to Penicillin

Of the adjuncts to penicillin the first and most important is time. 5M+6 months does far more than 5M alone, and in all my more recent cases I have been content to allow intervals of this order before re-examining the cerebrospinal fluid and considering the need for further therapy. Most observers have not given time its opportunity before going on to malaria, but those who have describe very good results.

The second most important adjunct is probably more penicillin. However, until we know the full value of time after the first course it is impossible to say just how valuable a second course is. Effects that were attributed to repetition of the penicillin in Cases 5 and 7 may well have been due in fact to time.

As other adjuncts I have used N.A.B., bismuth, mercurial inunction, and a mercury and iodide mixture in different cases. N.A.B. has been used in three cases in the desire to obtain a negative Wassermann reaction in the blood, since penicillin seemed to have a peculiar weakness in that respect. Mercury and iodide possibly exert a better effect than anything else on the more subacute or chronic pathological formations in meningo-vascular syphilis, and if this is so they have a special place in the treatment.

Tryparsamide I have not as yet used as an adjuvant to penicillin, and until we can assess more exactly the effects of penicillin itself it would be impossible to determine its value in combination, but it obviously may have a place.

Comparison with Malarial Therapy

To revert to the more active of our cases—those with mental symptoms and "paretic" fluids and those with optic atrophy—we have to consider the two burning questions: Are the results as good as those that would have been obtained with malaria? and, secondly, Could the results be improved by giving malaria as well?

In times past, eight at least, and probably ten, of these patients (including those with optic atrophy) would have received malarial treatment. Would the results have been any better? My own experience says that they would not have been as good, and actually in the last half-dozen cases treated by my colleagues with malaria at Queen Square the serological results to date are not as good as those of the cases treated with penicillin alone. We must bear in mind both the limited effectiveness of malaria and the dangers and difficulties of the treatment. Malaria alone is effective in the sense that it arrests the disease in general paralysis in about 55% of cases, and the remaining cases gradually progress so that 40% of all the patients treated die within five years. The mortality associated with the period of malarial treatment and the subsequent months is 8-10%. The results are considerably improved by combining tryparsamide with malaria, but even with the combination the disease is not arrested in all cases. With penicillin therapy the risks and difficulties of treatment are obviously very much less, and if the results obtained are at all comparable, as they undoubtedly are, the advantages are very conspicuous. I do not overlook the fact that my own small series contains no case of acute G.P.I., but Nicol and Whelan (1947) in this country, and also Smith (1947), have reported great clinical improvement in such cases with penicillin alone.

The American reports are mixed, but Callaway and his associates (1946) considered that treatment with penicillin was more effective than with malaria, and Rose and others (1946) concluded that there was little to choose between the results obtained with penicillin alone and those with malaria followed by tryparsamide. Daitner (1947) considers that penicillin when given in adequate doses is at least as effective in the treatment of neurosyphilis as combined fever and specific chemical therapies. A more detailed account of the American reports has recently been given by Dr. Worster-Drought (1947), and now we have a shorter review by Dr. Nicol (1948).

But there is the further question, Would still better results be obtained by giving malaria as well? Or rather, would any improvement commensurate with the risk be obtained by giving malaria as well? In the last resort this question may be settled by practical experience, and from the reports that have been published of comparable series of cases treated by different methods it is evident that there is no great difference in the results. In a series described by Rose and Solomon (1947) there was no material difference in the percentages of clinical improvement whether the patients were treated with penicillin and malaria, penicillin and the fever cabinet, or penicillin alone. From the report of a smaller series described by Lescher and Richards (1947) in this country it is also evident that the results were very similar, although the observers concluded that the best clinical results seemed to have been achieved with malaria and penicillin, closely followed by those obtained with penicillin alone.

There are two general aims in treatment. The first is to obtain arrest of the disease as rapidly as is possible in consistency with safety, and the second to ensure its permanence. If a rapid arrest can be obtained by any means, additional treatment for the same purpose is useless, and if it involves risk it is certainly unjustified. Treatment cannot

of the cerebral tissue: it can only arrest the disease. Arrest as rapidly as is consistent with safety is the only requirement. It seems that the syphilitic processes are arrested by penicillin before malaria could even come into operation, although further experience is necessary to show whether that inhibition is complete enough in all kinds of cases.

It is fallacious to say that clinical recovery occurs more quickly or more completely after this or that method of treatment, provided only that the treatment is effective—i.e., that it eradicates the disease. After any sufficiently effective treatment the extent of clinical recovery depends on the amount of the cerebral tissue that is capable of recovery, and that is not a function of the treatment but of the viable cerebral tissue. Similarly, the period of clinical recovery is the time required for the recovery of such cerebral tissue as is capable of restored activity. The final results cannot vary between one effective method of treatment and another, provided the treatments themselves are innocuous and reasonably prompt in their actions; and if an effective treatment has once been given no greater or quicker improvement can possibly be obtained by a multiplication of therapies. The practical results that have been reported are in general agreement with this conclusion.

Secondly, to ensure its permanence. Here our only criterion is the serological reactions. After the disease is arrested these take time to become normal, and if the cerebrospinal fluid is of the "inactive" type after three or four months, and normal, apart from the colloidal gold reaction, within a year, we may be satisfied. Such results are obtainable with penicillin as with malaria, and there seems no reason why they should not be as permanent. Though serological relapses must be watched for, they are likely to be few.

Conclusions

As a result of my observations I draw the following conclusions—tentative because longer observation is necessary.

1. Penicillin alone is sufficient in most cases of neurosyphilis. Whether it is adequate for the most acute cases of G.P.I. the experience of this series does not show.
2. If, with the possible exception of such cases, the patient can be kept under observation after treatment and penicillin repeated if necessary, malaria will seldom be called for, and the risk of it will seldom be justified.
3. Even if penicillin does not render malaria unnecessary it is a potent weapon and will make us much less dependent on malaria, and, if malaria is used at all, risks which were hitherto before need not now be taken.

A CASE OF ACUTE PORPHYRIA

BY

ERNEST PETRIE, B.Sc., M.R.C.P.

Registrar, Postgraduate Medical School, London

"Acute idiopathic porphyrinuria is clearly recognized in Germany and elsewhere on the Continent; it is being increasingly reported in America, but even to-day it is scarcely mentioned in British literature." The above comment, made in 1939 by Chandler *et al.*, appears as true to-day as it did eight years ago. It has been suggested by clinicians (Rau, personal communication, 1947) who are familiar with the condition that the relatively large number of cases reported in Scandinavia and Germany was primarily due to a more widespread knowledge of the chief features of this rare metabolic disorder. This interest was particularly stimulated by the clinical investigations of Günth (1911), who first described the disease, and by Haas and Fischer's elucidation of the chemical nature of porphyrin pigments. The comprehensive reviews of Mason, Cottrill, and Ziskind (1933) and Dobriner and Rhoads (1939) have recently served to stimulate in America an increased interest in the chemical and clinical aspects of this malady. A brief survey disclosed that no fewer than 36 reports had appeared in the literature in America since 1940, when only three indigenous cases have been recorded in British medical journals during the same period. A fourth British case, the chemical aspects of which were fully investigated, was recorded by Prunty (1946) in an American journal.

In man clinical porphyria occurs in the form of two distinct syndromes—congenital porphyria (Garrod, 1922) and acute porphyria.

Congenital Porphyria

This is a very rare disease that develops during foetal life. It is usually recognized in early infancy, and persists in the adult as a permanent disorder of metabolism. Transmission is thought to occur by the inheritance of a gene possessing recessive characteristics (Mackey and Garrod, 1926). Salient features are the excretion of burgundy-coloured urine and a disabling degree of photosensitivity of skin and exposed mucous membranes. Brown pigmentation of bones and pink discoloration of deciduous and permanent teeth have occasionally been recorded (Mackey and Garrod, 1926). Exposure to bright sunlight leads to blistering of unprotected skin and the formation of ulcers, indolent healing of which results in permanent disfigurement by scar tissue. Corneal ulceration due to similar action of trauma may lead to seriously impaired vision. Both splenomegaly and hepatomegaly have been recorded as transitional features in childhood. In this condition excess of uroporphyrin I is excreted.

Acute Porphyria

The symptomatology of this disease, which affects adults, differs entirely from that of the congenital variety. Acute porphyria occurs more frequently in women than in men, and the onset is most often during the third decade. It is probable that the symptoms of acute porphyria are merely acute manifestations of a latent chronic metabolic disorder whose asymptomatic phase can be detected only by special investigation of the excreta. The acute and dramatic manifestations of the classical syndrome appear either spontaneously or as a result of prolonged ingestion of certain drugs, of which sulphonal is most commonly incriminated. It thereafter may pursue a prolonged relapsing course, which often ends fatally. Many recorded cases have been sporadic examples, but recent

Examinations in Perth Green, Oxford House and University College, London, are held for students for studying social conditions there. The student is brought into intimate contact with the life of the community with the working or serving behind the scenes. The course is held on July 1-24. The fee is 4 guineas, and the student is provided with the necessary equipment. Further information may be obtained from the Vice-Chancellor, Oxford House, 1, The Quadrant, Oxford.

an increasing number of reports have indicated that the disease may occur as a familial condition (Nesbitt, 1944). There are factors in the case history recorded below which strongly suggest a familial incidence. It is thought that the inheritance of this disorder is by transmission of a dominant gene (Gates, 1946) whose degree of penetrance is small. Hence this undesirable characteristic may be acquired from a parent who discloses no clinical or metabolic abnormality.

The symptoms of acute porphyria tend to be remarkably stereotyped. The initial attack may be preceded by a prodromal period during which weight is lost and asthenia is pronounced. During this phase various *mental disturbances*—most frequently depression, irritability, or suicidal tendencies—have been notable features. *Abdominal symptoms* follow. There is usually severe para-umbilical colic or lower abdominal cramp-like pain, often associated with nausea and vomiting. Obstinate constipation amounting to a paralytic ileus is constantly present. The abnormal colour of the urine is usually noticed only after the onset of these symptoms, but frequently the significance of this observation is masked by the presence of concomitant icterus. Occasionally patients will admit having excreted dark urine intermittently long before the onset of the illness. A raised blood pressure is a consistent feature at this stage. It is often as high as 180/120, and its discovery in a young adult presenting severe abdominal pain without other localizing features should lead to examination of the urine for porphyrins.

Recovery may occur without further progression of the disease, but relapses are usual, and eventually in about half the cases evidence of *involvement of the central nervous system* appears (Waldenström, 1937). Coma, psychosis, delirium, amaurosis, and epileptic attacks are frequently associated with the more characteristic progressive impairment of motor function. Isolated cranial-nerve palsies, localized weakness of peripheral muscle groups, and more generalized motor involvement develop. Although paraesthesia is usually a marked feature, cutaneous sensibility remains intact. The intensity of the muscular weakness may fluctuate unaccountably, and spread of the paresis to the respiratory muscles, through bulbar involvement, usually terminates the illness. Although photosensitivity and pigmentation of the skin have been recorded in acute porphyria (Nesbitt and Watkins, 1942) they are both regarded as unusual features.

Excessive urinary excretion of uroporphyrin III characterizes most cases of acute porphyria (Waldenström, 1937). On occasion, however, the urinary uroporphyrin III is within normal limits, whereas uroporphyrin I (Prunty, 1946) or coproporphyrin III (Abrahams *et al.*, 1947; Watson *et al.*, 1945) is excreted in excessive amounts.

Case Report

A British soldier aged 26, who had served in the Mediterranean area since 1942, first observed symptoms of ill-health in December, 1946. He noticed that he was lacking in energy, that his limbs, previously very muscular, were now no longer so, and that his uniform had become too loose for him. In spite of increasing weakness, he remained on duty until March 2, 1947, when he was forced to take to his bed with symptoms which were then regarded as being due to "coryza." He was a little better next day and was able to get up, but three days later he was in bed again because of difficulty in standing.

He was admitted to a casualty clearing station seven days after the onset of these acute symptoms. His chief complaints were: central abdominal pain for 24 hours and constipation for three days, a generalized weakness, difficulty in concentration during the day, and sleeplessness at night. It is reported that when first examined at the C.C.S. the patient's condition was extremely poor. He was nauseated and very drowsy; pulse 120, temperature 97° F. (36.1° C.), respirations 20. He was severely

dehydrated. The abdomen was distended, epigastric tenderness was present, but there was no rigidity. Liver and spleen were not palpable. The respiratory system was normal, as was the cardiovascular system except that the blood pressure was 140/90. The pupils were constricted, but reacted normally to light and accommodation. All the tendon reflexes were obtainable and the plantar responses were flexor. In spite of obvious muscular wasting, power was good. There was no sensory loss. A generalized superficial lymph-node enlargement was thought to be due to the septic scabies present. The urine contained no sugar or albumin. Total leucocyte count, 22,400 per c.mm. (polymorphs 92%, lymphocytes 3%, monocytes 5%).

On re-examination the following morning a generalized pigmentation of the skin was noticed. The knee- and ankle-jerks and abdominal reflexes were now unobtainable. The left plantar response was equivocal. Lumbar puncture was performed. The pressure was normal and the fluid clear. Protein amounted to 35 mg. per 100 ml. There was no excess of globulin.

During the next few days the patient's condition, which remained critical, showed little change. Slight icterus of the conjunctiva was noticed on March 12.

On March 18 he was transferred to a British general hospital. The pulse was now 104, temperature 97° F., respirations 25, blood pressure 150/100. Lethargy was still marked, but the patient responded rationally to interrogation. Loss of power in all limbs was noted for the first time. All tendon reflexes were present except for the Achilles jerk. Plantar responses were both equivocal. There was no loss of cutaneous sensibility. The intense brown pigmentation of the skin was again a subject of comment, and it was suggested that it might be of pellagrous origin. With this in mind, and with the intention of demonstrating the associated excess porphyrin, two specimens of urine were allowed to stand exposed to the light for 24 hours, but no deepening of colour was observed. Owing to subsequent lack of response to nicotinic acid therapy, no further investigations into this aspect of the problem were made, nor were any pigmentary abnormalities detected during further routine laboratory examinations of the urine. By mid-April the gradually increasing weakness had proceeded to a stage in which limb movements were almost completely absent. Speech was slurred, but there was no dysphagia. The corneal reflexes were absent, as were all tendon reflexes, although cutaneous sensation was still unimpaired. Muscles were slightly tender to pressure. Lumbar puncture was repeated. Pressure was normal; protein totalled 70 mg. per 100 ml. with excess globulin; and there were 2 cells per c.mm. By this time an extensive series of investigations had been completed. Radiographs of the chest, repeated cultures of blood, urine, faeces, and throat, blood examinations for malaria parasites, and serum agglutinins disclosed no abnormality. Fasting blood sugar was 140 mg. per 100 ml., blood urea 90 mg. per 100 ml., serum protein 5.8 g. per 100 ml., van den Bergh reaction negative, haemoglobin 95%, and E.S.R. 32 mm. in 1 hour.

At this stage 10 ml. of "eucortone" was administered each day without any therapeutic response. "Prostigmin," 0.5 mg. intramuscularly three times a day, was equally ineffective in relieving the profound asthenia. During the first few days of April the patient remained extremely feeble. There was incontinence of faeces and urine; drowsiness during the day was increasing, whereas insomnia at night remained a troublesome feature in spite of sedation with barbiturates. At times attacks of tachycardia and breathlessness occurred. A slight improvement began in the second week of May, and his condition, although still very serious, permitted transfer to England.

The patient was admitted to Redhill County Hospital on May 18. He was a mentally alert individual showing very severe emaciation and extreme loss of muscle substance. The most striking feature, however, was a dusky pigmentation, which was most marked on the face but was also present on the arms and thorax, and to a less extent on the abdomen and legs. The hair was dark brown. (It was later established that his complexion had always been fair, and that when on leave in November, 1946, the dark colour of his hair and pigmented features had astounded his relatives.) The skin was scaly, and lesions of scabies were still present. There were hyperkeratotic patches on the flexor aspects of the fingers and on the palms and soles.

Central Nervous System.—Mentality normal. Amnesic for events occurring during early part of illness. Not aphasic, but could articulate only in a whisper. Pupils unequal, right larger than left; both reacting normally to light and accommodation. Fundi normal except that the arteries and veins were abnormally contracted. Eye movements were full and visual fields normal. No nystagmus. The muscles of mastication were of normal power. Extreme weakness present in all facial muscles, particularly frontales and orbiculares oculi, so that the cornea was always exposed, even during sleep. There was severe conjunctivitis and keratitis of both eyes. The palate moved normally and there was no dysphagia. The tongue, which was normally protruded, was wasted and deeply furrowed, with coarse fasciculation evident. Sensation of taste was not impaired. The right vocal cord moved normally, the left very sluggishly. The cervical muscles were of fair power, and the intercostal and diaphragmatic movements of normal range. All four limbs were flaccid and lay in positions dictated by gravity. There were weak movements of finger flexion in the left hand only. Except for ineffectual contractions of the upper fibres of both pectorales major, the muscles activating the shoulder-, elbow-, and wrist-joints were completely paralysed. The lower limbs retained fair power in the glutei, tensorae fasciae latae, hamstrings, and posterior tibial muscles. Contractility of the quadriceps femoris, which were barely palpable as thin straps on the femur, was absent. Anterior tibial and peroneal groups likewise were totally paralysed. There was fair power of flexion of the toes. The deep and superficial reflexes were all unobtainable. The plantar responses, in the absence of contractility of the extensors of the toes, were necessarily flexor. There was no fibrillation of muscles other than the tongue. Complete faecal incontinence, but normal bladder control, was present. There was no sensory loss.

The pulse was regular 96, the blood pressure 110/80, and heart normal. There was no abnormality in the respiratory system. The liver and spleen were not palpable. The descending colon was palpable and spastic.

Investigations. The combinations of inaugural abdominal symptoms with cerebral disturbances, evidence of lower-motor-neurone paresis, and cutaneous pigmentation led to the examination of the urine for porphyrins. Spectroscopic investigation of a freshly passed specimen showed the typical double band of the zinc porphyrin complex (Chandler *et al.*, 1939). Ehrlich's benzaldehyde test (Jorgensen and With, 1947) before and after extraction of the urine with acid ether was positive, indicating the presence of porphobilinogen. An amyl alcohol extract of the urine displayed intense pink fluorescence when exposed to Wood's light, as did a specimen of faeces. Urine when first voided was the colour of sherry, and on standing it assumed a dark coffee colour in 24 to 48 hours.

Further investigations resulted as follows: haemoglobin, 95 g. (R.H.C. 4,500,000), colour index, 1.04; leucocytes, 8,000 per c.mm. (polymorphs 34%, lymphocytes 55%, monocytes 4%, eosinophils 7%); blood urea, 68 mg., fasting blood sugar 94 mg. and blood cholesterol 124 mg. per 100 ml., Kahn, trace; Wassermann +, Laughten ±. Total plasma protein, 5.25 g. (albumin 2.8 g., globulin 2.45 g.), chloride 343 mg., potassium 18.4 mg., and sodium 321 mg. per 100 ml., carbon-dioxide-combining power, 57 vols., serum bilirubin, 0.4 mg. per 100 ml. Thymol turbidity test, negative. Alkaline phosphatase, 2.4 B.S. units. Cerebrospinal fluid: pressure normal; protein, 60 mg. per 100 ml.; Pandy, trace; chlorides, 680 mg. per 100 ml.; lymphocytes 1 per c.mm.; W.R. negative; Benzoin reaction (Gunn). The electrocardiogram was normal. Sternal-catheter examination showed normoblastic haemopoiesis with evidence of hyperplasia of erythroblastic elements. The white-cell sedimentation was normal. Exposure to bright July sunlight for 45 seconds in an intense irritation of the skin and marked erythema, both of which persisted for an hour. Exposure to a mercury-vapour ultra-violet lamp for half an hour had no effect.

Family History. The patient's mother stated that she had no history of any urinary abnormality in herself or in her family. Her father had experienced attacks of colic. The patient's father died at the age of 29. The maternal grandfather, who was a painter by occupation, died at 25. The cause of death was "painter's

colic." One sister, two stepsisters, and a stepbrother were healthy, as was the patient's son, aged 6 years. An attempt to investigate the urine of these individuals met with formidable opposition. Nevertheless specimens were obtained from the patient's son, mother, and sister. No abnormal pigments were detected in the urine of the son and mother, but that of the sister was deeply coloured, darkened slightly on standing, and reacted positively with Ehrlich's benzaldehyde reagent after ether extraction, indicating the presence of porphobilinogen. Schlesinger's test on the same specimen was negative.

Progress.—During the two months that the patient remained at Redhill County Hospital there was a slow but steady improvement in his state of nutrition, and his sleep habit rapidly reverted to normal rhythm. Except for return of contractility, so slight as to be ineffective, in muscles which previously had been quite inert, increase of muscle power did not occur. There was a considerable decrease in the depth of colour of the urine when first passed, and the final depth after standing was less than it had been on admission, but the spectral bands did not indicate that any reduction of porphyrin excretion was occurring. The improvement noted appeared to be independent of the treatment given, which consisted in the serial intramuscular administration of liver preparations, folic acid, and calcium gluconate.

Five 24-hour specimens of urine were collected between June 15 and 19 and submitted to Prof. C. Rimington, who confirmed the presence of excess porphyrin and identified it as uroporphyrin III. Coproporphyrin was present in normal amounts. The excretion of uroporphyrin on the five days was 9.7, 9.4, 8.6, 8.3, and 9.5 mg. respectively. The patient was transferred to an E.M.S. hospital near his home on July 14. A progress report from that hospital stated that a relapse had recently occurred, during which power in all muscles, except those innervated by the cranial nerves and those subserving respiration, was quite absent. Colic and nausea were again conspicuous features, as was a marked hypotension, the latter responding to eucortone.

Comment

This case, which presented many of the typical features of acute porphyria, illustrated particularly clearly the nature of the diagnostic problem confronting the clinician when neurological symptoms and signs are pre-eminent. When abdominal symptoms predominate, as they often do, errors in diagnosis have led to injudicious laparotomy. The difficulties in the differential diagnosis of these rare cases presenting a tangle of features referable to many of the bodily systems may be totally resolved by the discovery of abnormal pigments in the urine. Nesbitt (1944) states that "the diagnosis of acute porphyria will be made only if it is borne in mind." The view that acute porphyria is an inborn familial metabolic disorder is supported by the evidence in the above case.

It is thought probable that the grandfather's fatal illness was acute porphyria and not "painter's colic," which it may closely simulate. Porphobilinogen was demonstrated in the urine of the apparently healthy sister, emphasizing that it is important to search for latent porphyria among relatives of the acute case. These individuals should be warned not to take drugs which have been known to precipitate the acute condition. According to Dobriner and Rhoads (1940) the following drugs are suspect: sulphonal, "trional," sulphonamides, barbiturates, arsenicals, alcohol, phosphorus, selenium, and lead. It is noteworthy that, although there is no direct evidence of any causal relationship, mepaeirine had been taken by the patient as a malarial prophylactic during the previous three summers. His critical condition prevented investigation of the effect of a provocative dose of this drug.

Although pigmentation and photosensitivity were marked features of this case, both of these effects are rare in acute porphyria (Mason, Courville, and Ziskind, 1933).

Summary

An example of acute porphyria occurring in a young man is described. Abdominal and mental symptoms and neurological signs were present. Pigmentation and photosensitivity were conspicuous features. There was some evidence of a familial distribution of the disease.

I am indebted to Dr. G. H. Jennings for his encouragement and permission to publish this report; to Prof. C. Rimington for his kindness in performing the assays; to the R.A.M.C. officers whose notes furnished the basis of the early part of the case history; and to Miss E. W. M. Johnson for her help with the biochemical investigations.

A CASE OF ACUTE MONONITROBENZENE POISONING

by

J. D. N. NABARRO, M.D., M.R.C.P.
 Medical Registrar, University College Hospital

Mononitrobenzene, or oil of mirbane, is a yellow oily liquid which on account of its strong smell is also known as "artificial essence of bitter almonds." Since it was first prepared early in the nineteenth century many cases of poisoning with this substance have been recorded—by absorption through the skin, by inhalation, or when taken by mouth.

Poisoning by skin absorption has followed the use of soap scented with it (Nicholson, 1862), spilling the fluid on the clothes (Loeb, Bock, and Fitz, 1921; Hamilton, 1919–20; Letheby, 1863–4), or application to the hair of anti-louse preparations made with it (Wolpe, 1920; Bohland, 1919; Schultz, 1915). Shoe dyes often contain nitrobenzene as a solvent, and the wearing of recently dyed shoes before they are properly dry has led to many cases of poisoning. Muehlberger (1925) has reviewed the literature on this subject and pointed out that aniline is the solvent most commonly employed, and may give rise to similar symptoms. Levin (1931) has reported a case of orthotoluidine poisoning caused in the same way. Marking-ink also may be prepared with nitrobenzene or aniline, and babies seem to be very easily affected by newly marked napkins: Rayner (1886) first reported a series due to aniline, and Ewer (1920) and Thomsen (1921) have reported cases due to nitrobenzene. In many of these episodes inhalation may have contributed to the intoxication: acute poisoning due to inhalation alone is relatively infrequent, but Stevenson and Forbes (1942) and Stevens (1928) have reported cases following the use of nitrobenzene in bed-bug exterminators.

Poisoning by ingestion has occurred in numerous ways. The majority of cases are accidental, either errors in dispensing (Carter, 1936; Leader, 1932; Thomas, 1926) or mistakes by patients as reported by Chapman and Fox (1945), where furniture polish containing nitrobenzene was taken instead of an alkaline stomach mixture. Hogarth (1912) published a case following the rubbing of nitro-

benzene on the gums as an anodyne for toothache. Other cases have arisen from taking alcoholic drinks which have been contaminated with the substance (Loeb, Bock, and Fitz, 1921; Scott and Hanzlik, 1920) or from drinking a nitrobenzene preparation when intoxicated (Adler, 1934; Wandel, 1919). Food contaminated with the liquid is a rare cause (Hilbert, 1915), though Taylor (1864) reported the case of a woman who tasted the flavouring she was going to use in some pastry and developed nitrobenzene poisoning. Curiosity on the part of children accounts for some cases (Nobécourt and Pichon, 1924); a few are suicidal (Fullerton, 1930; Schild, 1895); and on many occasions the liquid has been taken as an abortifacient, usually without success (Güntz, 1930; Schnopf, 1927; Spinner, 1917; Schild, 1895).

Chronic poisoning is usually industrial. Workers in aniline plants may develop symptoms from nitrobenzene inhalation; it is less common than aniline intoxication, but is more dangerous when it does occur. Engel (1934), Balzac *et al.* (1930), Hamilton (1919–20, 1921), and Letheby (1863–4) have discussed industrial nitrobenzene poisoning, and Adams (1912) has described an unusual case of non-industrial chronic intoxication.

Case Report

The patient, a Polish girl aged 19, was admitted to University College Hospital on July 23, 1947. About three months previously, while she was in Germany as a displaced person, she had married an English soldier, who brought her to London and left her with her mother-in-law while he returned to his unit. She did not get on very well in her new home, and partly out of curiosity and partly, one suspected, hoping to get her husband repatriated she decided to taste the fluid in a bottle labelled "poison." This bottle had been bought by her late father-in-law many years previously and was lying about the house; her husband had warned her that it was poisonous and forbidden her ever to touch it. About 6.30 p.m. on July 22 she poured some of the fluid into a glass and sipped it; she felt nauseated, and vomited several times during the night. The next morning she was seen to be blue, and was therefore sent to hospital.

When seen at 3 p.m. on July 23 she was fully conscious and well orientated. She showed "blue-grey" cyanosis and was vomiting repeatedly, the vomit being bright yellow, but without smell. She was afebrile; pulse rate 90; respiration was of normal depth and rate, but the breath smelt strongly of almond essence. Physical examination revealed no other abnormalities. The urine was dark in colour and became darker on standing; it contained a trace of albumin and did not reduce Benedict's reagent.

The stomach was washed out with saline, after which the vomiting ceased. Oxygen inhalations failed to affect the cyanosis, and blood withdrawn from a vein was brownish in colour and shown to contain methaemoglobin. 20 ml. of 0.5% solution of methylene blue was injected intravenously and within 30 minutes the patient's colour was restored to normal.

The next day (July 24) her breath still smelt of almond essence and continued to do so until July 27. The cyanosis was then nearly as deep as before the injection of methylene blue, but it did not seem to be inconveniencing the patient. Oral methylene blue, 2 gr. (130 mg.) four-hourly, was given for two days, and subsequently ascorbic acid, 100 mg. four-hourly, but neither of these seemed to accelerate the disappearance of the cyanosis, which ceased to be detectable on July 29. The urine on July 25 was of normal colour, but still contained a trace of albumin.

On July 29 it was observed that the patient was faintly icteric, and that a severe haemolytic anaemia was developing (see Chart). On July 30 and 31 she passed urine that was almost black, and spectroscopic examination showed that it contained haemoglobin and methylene blue; a sample of plasma on the latter date contained methaemalbumin and haemoglobin. Red cell fragility showed haemolysis starting at 0.48% saline and complete at 0.28%, and a blood film revealed very marked anisocytosis, polychromasia, punctate basophilia, and six

calculated red cells per 100 white cells. By July 31 her blood pressure had fallen from its initial level of 110/85 to 98/50 and her pulse rate had risen to 104; it was therefore decided to give a transfusion of 2 pints (1.136 litres) of blood. Her condition subsequently improved rapidly, and she left hospital on Aug. 8. When seen on Aug. 25 she had no symptoms.

Chart showing haemolytic action of nitrobenzene.

The bottle from which the fluid was taken contained a yellow oily liquid smelling strongly of almond essence and rather indistinctly labelled "nitrobenzene." That the bottle contained nitrobenzene was subsequently confirmed chemically. It was impossible to ascertain the purpose for which it had originally been obtained.

Discussion

Nausea and vomiting are the first symptoms after the oral ingestion of nitrobenzene; they develop within a few minutes and are followed in from one to twelve hours by the appearance of cyanosis and in severe cases by neurological symptoms. In cases of poisoning by skin absorption or inhalation the cyanosis develops more rapidly. It is now generally considered that the cyanosis is due to the development of methaemoglobin in the red blood cells, although many earlier investigators—for example, Loeb, Bock, and Fitz (1921)—were unable to detect methaemoglobin in the blood, and postulated the development of a nitrobenzene haemoglobin compound. Hamblin and Mangelsdorff (1938) devised a recording spectrophotometer and used this to detect methaemoglobin, which they found in the blood in all cases of nitrobenzene poisoning in amounts proportional to the clinical condition and cyanosis.

The neurological symptoms that may be seen in the early stages are progressive drowsiness leading to coma and in fatal cases respiratory paralysis. These have been attributed either to a direct toxic action of the poison on the central nervous system or to anoxaemia. Loeb, Bock, and Fitz (1921) reported the case of an unconscious patient with a blood-oxygen-carrying capacity of 6.2 volumes % who recovered consciousness on being given a blood transfusion, although cases have been reported showing spontaneous recovery from nitrobenzene coma (Güntz, 1930), it is suggestive that in this case recovery was due to improved oxygenation following the transfusion. Steele and Spark (1933) report a case of aniline poisoning with coma and cyanosis in which recovery of consciousness followed the intravenous administration of methylene blue, which converted the methaemoglobin to haemoglobin and increased the oxygen-carrying capacity of the blood. Howland and Leach (1927), in investigations of the effect of nitrobenzene on animals, found that, whereas dogs, cats, and

and guinea-pigs failed to develop cyanosis but nevertheless died. It appears therefore that, although anoxaemia may play a part in the production of neurological symptoms and death, a direct toxic action on the nervous system is an important factor.

In all moderately severe cases of nitrobenzene poisoning some haemolysis is found, starting about the fifth or sixth day. Engel (1934) mentions that the haemoglobin level may fall to 30%; Leinoff (1936) records a case in which it was 45%. Clinical icterus is present when haemolysis is severe and the spleen occasionally becomes palpable (Hilbert, 1915; Schild, 1895). The process is usually self-limiting, and blood transfusion is not often required.

Late sequelae are unusual in cases of acute poisoning, although Adler (1934) reported a case in which a neurological disturbance suggesting a lesion of the basal ganglia followed four days' unconsciousness due to nitrobenzene; and Grafe and Homburger (1914) reported a case in which mental deterioration was a sequel. It is possible that in the first case prolonged cerebral anoxia was an important factor.

Laboratory Investigations

In the early stages spectroscopic examination of the blood is useful in confirming the presence of methaemoglobin. A daily red cell count is advisable to ascertain the severity of the haemolytic process. Haemoglobin estimations are satisfactory if done by the Sahli method, but in this case only that of Haldane was available, and although the results are recorded in the Chart the presence of methaemoglobin makes them unreliable. The white blood cells may show a polymorphonuclear leucocytosis in the early stages, and Loeb, Bock, and Fitz (1921) report 40,000 per c.mm. in one case; a second rise during the haemolytic phase may also be found.

The urine initially may be dark, especially on standing; this has been noted on many occasions, and, according to Loeb, Bock, and Fitz (1921) and to Meyer-München (1905), is due to nitrobenzene being excreted as para-amidophenol. It is often said that the urine may contain a reducing substance, but this is rarely reported in case summaries, although Wolpe (1920) stated that one of his patients had 0.1% sugar in the urine the day after poisoning (method of testing not mentioned). Engel (1934) attributes this property of the urine to the presence of glycuronic acid, with which para-amidophenol is conjugated for excretion. The passage of dark urine in the haemolytic phase is unusual, although Güntz (1930) mentions it in his case.

Treatment

The recognition of acute nitrobenzene poisoning should not be difficult with the extreme cyanosis and characteristic smell, and if the history suggests oral ingestion the stomach should be washed out. If the patient is unconscious, steps should be taken to restore the oxygen-carrying capacity of the blood, a procedure which may terminate the coma although it will not affect the direct toxic action on the nervous system. Blood transfusion and replacement transfusion have both been used with good results: Chapman and Fox (1945) had a patient in semicoma who was much improved by venesection and transfusion of 3 pints (1.7 litres) of blood. In view of the ability of methylene blue to convert methaemoglobin to haemoglobin, such measures would seem to be unnecessary, although in the case of replacement transfusion it has the theoretical advantage of reducing the amount of poison acting on the nervous system. Methylene blue was first advocated as a result of animal experiments for use in cyanide and carbon monoxide poisoning. In the latter it was considered to improve cell metabolism, whereas in the former it was thought to convert

haemoglobin to methaemoglobin, which fixed the cyanide and prevented its toxic action (Wendel, 1933). However, despite this evidence, Steele and Spink (1933) used methylene blue in two cases of aniline poisoning with dramatic disappearance of methaemoglobinaemia, and Williams and Challis (1933) in one case. Subsequently Wendel (1937) agreed that it had this action in man in the dose used; and Hartman, Perley, and Barnett (1938) made a detailed study of it as an antidote for methaemoglobinaemia following sulphonamide therapy. Only two reports have been found of its use in nitrobenzene poisoning. Walterskirchen (1939) employed an unstated amount of 1% solution of methylene blue intravenously, and the cyanosis cleared in 15 minutes. and Leinoff (1936) gave 30 ml. of a 1% solution intravenously, and describes the patient as at first becoming darker blue, then within one hour the condition improved and the finger-nails became pink. He does not mention a return of the cyanosis, but this is implied in the subsequent statement that it disappeared completely in a few days. The dose given in the case reported here is much smaller than that advised by Hartman *et al.* (1938)—1–1.5 mg. per kg. The subsequent oral administration had less effect than would have been expected in view of the finding of the same workers that 1–2 gr. (0.065–0.13 g.) four-hourly controlled sulphonamide cyanosis. The use of ascorbic acid was suggested by Deeny, Murdock, and Rogan (1943), who reported on its use in congenital methaemoglobinaemia and by Carnrick, Polis, and Klein (1946) in the acquired type, although in this case it was really given too late to say whether it was beneficial.

There does not seem to be any danger in giving methylene blue in these doses, although coloration of the urine may surprise the patient and injection outside the vein may cause a severe and painful inflammatory reaction.

Subsequently the extent of the haemolytic process must be watched, and, if the haematological or clinical condition demands it, blood transfusion should be given. In the present case it is probable that the haemolysis was maximal at the time of the transfusion and that the condition would have improved satisfactorily without it.

Summary

A case of acute nitrobenzene poisoning following oral ingestion is reported. Cyanosis and haemolytic anaemia were the outstanding clinical features. Methylene blue was used in the treatment of the methaemoglobinaemia, and the haemolytic anaemia was so severe as to need a blood transfusion.

I have to thank Dr. F. M. R. Walshe for permission to publish his case, and Dr. M. Maizels, Dr. M. E. Morgans, Dr. E. Roderic Evans, and Mrs. C. E. Work for the investigations.

HETEROTOPIC OSSIFICATION OF AN APPENDICULAR MUCCOCELE

BY

I. JUVARA, M.D., M.S.
 Surgeon

AND

U. BORCESCU, M.D.

From the Third Surgical Unit, Coltea Hospital, Bucharest, Rumania, under the Direction of Prof. D. Hortolomei.

By the term "heterotopic ossification" is meant the appearance of osseous tissue in an organ which has no ontogenetic relationship to the process of ossification. The spontaneous occurrence of heterotopic ossification has been observed in the most unexpected tissues and organs, as, for example, aneurysmal walls, old haematomata, laparotomy scars, injured muscles and nerves (Leriche and Policard, 1926), arterial walls (Monckeberg, 1902), tonsils (Reitmann, 1903), aortic valves (Rosenstein, 1900), the anterior chambers of the eyes (Koch *et al.*, 1939), tissues affected by elephantiasis (Kleine, 1929), and of course tumours (Leriche and Policard, 1926; Törö, 1935).

Experimentally, the condition has been obtained by ligation of the renal vessels, in granulation tissue by a variety of methods (Leriche and Policard, 1926), by grafting a portion of gall-bladder mucosa, urinary-bladder mucosa, or even gastric mucosa into various connective tissues (Cavalli, 1939; Jung and Cemil, 1935; Leriche and Lucinresco, 1935; Lucinresco and Cavalli, 1935, 1936; Santa and Maracci, 1938), or when a portion of an aponeurosis has been used to replace a defect in the urinary bladder wall (Neuhof, 1918–20; Huggins, 1931; Phemister: Copher and Key).

The mechanism of heterotopic ossification is still a matter of controversy. Conheim supported the theory of latent embryonic points of ossification; Ollier that of periosteal displacements; Busch, Macewen, and Ribbert that of the haematogenous seeding of osteoblasts. At present the hypothesis of Leriche and Policard is favoured—namely, that the principal requirements for the occurrence

FIG. 1.—Naked-eye appearance of the tumour.

Heterotopic ossification are the creation of a granulation tissue and the deposit therein of calcium salts, the processes occurring either together or in succession.

Slowing down of the circulation, produced by venous stasis, is a factor in fibrous ossification. Ischaemia is a factor in enchondral ossification (Giuliani, 1934).

Our present work deals with a case of heterotopic ossification of a mucocele of the vermiform appendix. This had opened into the peritoneal cavity and was associated with a platynous condition of the peritoneum (Péan's disease or Werthe's pseudo-mycomatosa peritonealis). The appendix was located in the sac of an inguinal hernia. The condition was discovered at an emergency operation for strangulation of the hernia.

Case Record

The patient, a man aged 70, was admitted to hospital on the 13th of May 1946, with strangulation of a right inguino-hermal hernia. The hernia first appeared six years before and had been strangulated twice. On each occasion reduction of the hernia was successfully carried out after one or two hours. On May 14, 1946, immediately after a muscular effort, strangulation occurred and repeated attempts by the patient to reduce the hernia were unsuccessful. He was admitted six hours after the onset of strangulation. On admission his general condition was good. The bowels had moved, and an irreducible hard, non-tender tumour was found on the right side.

Operation (Radical cure "percarine" and ephedrine). The sac was dissected out and the contents found to be stony hard.

On opening the sac, a stony hard, about 7 cm. long, was found, fixed to the ommentum at its upper pole. With a view to determining the nature of this tumour, the incision was extended superiorly and the abdominal cavity opened. A large, stony hard, irregular mass was found, fixed to the posterior abdominal wall. The mass was removed and the specimen was found to be a large, stony hard, irregular mass, fixed to the posterior abdominal wall. The mass was removed and the specimen was found to be a large, stony hard, irregular mass, fixed to the posterior abdominal wall.

FIG. 2.—For description, see text. (Giemsa stain; Oil-immersion objective No. 60, Zeiss.)

FIG. 2.—From above downwards: smooth-muscle tissue with fragments of epithelium; granulation tissue, with areas of calcification; osseous tissue. (Mann's stain; ocular $\times 5$; objective No. 3, Zeiss.)

The osseous body was found to be in direct connexion with a remnant of the appendix, approximately 1 cm. in length. The tumour and the appendicular remnant were removed and the operation finished by the method of Bassini.

Post-operative progress was normal and the patient was discharged after 12 days. A general examination of the patient six months later was satisfactory.

Pathological Examination of the Tumour.—The tumour (Fig. 1) was ellipsoidal in shape, about 7 cm. in length, opaque to x rays, and covered by soft tissues only over its upper pole. Microscopically it was seen to be a terminal atrophic portion of a vermiform appendix, with a tendency to sclerosis. The principal mass of the tumour consisted of three main histological elements—epithelium, granulation tissue, and osseous tissue (Fig. 2). The epithelium was of intestinal type and showed areas of hypertrophy and hyperplasia as well as of atrophy. These epithelial areas occurred in islands or in long strands. In some areas there were smooth-muscle fibres in relation to the epithelium. The lumen of the appendix, where it was still visible, was filled with an amorphous material which took up a rose-red colour when stained with Mayer's mucicarmine. The granulation tissue was situated between the epithelium and the osseous tissue. It showed areas of necrosis near the epithelium and of calcification near the osseous tissue. It could be clearly seen that calcium salts were being deposited in the necrotic areas, and that ossification was occurring in the calcified zones, where osteoblasts penetrated through connective-tissue trabeculae (Fig. 3). Peripherally the osseous tissue was contiguous with and external to the calcified zones. It contained typical bone

tion tissue was situated between the epithelium and the osseous tissue. It showed areas of necrosis near the epithelium and of calcification near the osseous tissue. It could be clearly seen that calcium salts were being deposited in the necrotic areas, and that ossification was occurring in the calcified zones, where osteoblasts penetrated through connective-tissue trabeculae (Fig. 3). Peripherally the osseous tissue was contiguous with and external to the calcified zones. It contained typical bone

cells and medullary spaces having blood capillaries and scanty haemopoietic cells. The direction of the Sharpey fibres showed clearly that the osseous tissue had been subjected to continual mechanical stress.

Discussion

In retrospect the condition is considered to have been a perforated appendicular mucocoele (in the sense used by Ferret in 1876) for the following reasons. There was a gelatinous condition of the peritoneum, and the pedicle of the tumour consisted of an appendicular remnant. On section the tumour showed portions of intestinal epithelium and mucous cavities.

The case can be considered to be a fortuitous experiment presenting the following features: the presence of an epithelium in a connective-tissue medium with a reduced circulation; mucoid impregnation of the whole structure; the development of a granulation tissue and of areas of necrosis in the wall of the appendix. The regular fibrillary structure shows, further, that some of the changes are due to traction or pressure by the intra-abdominal viscera, to intestinal peristalsis, and to traction by omental adhesions.

The role of the epithelium in heterotopic ossification is known from experiments. The experimental transplantation of mucous tissues into connective-tissue media constantly results in hypertrophy and proliferation of the mucous epithelium. Sometimes the epithelium may be responsible for the secretion of a phosphatase (Lucinresco and Cavalli, 1935, 1936; Severi, 1939). Zones of necrosis are the usual sites of calcification. The histocytes of the granulation tissue represent the source of the osteoblasts. Physiological studies have long ago shown that mucous substances and mechanical irritants have an osteogenetic effect. But even now there is no explanation of how haemopoietic tissue develops in relation to areas of heterotopic ossification.

Perusal of the literature revealed reports of calcification in appendicular mucocoeles (Henke and Lubarsch, 1929; Olanescu *et al.*, 1942) and of three cases of actual ossification (Henke and Lubarsch, 1929). Two of the latter were published by Nishii and Akimoto (1928)—appendicular carcinomata associated with mucocoeles, where osseous tissue appeared only in areas free of the invading neoplasm. The third was published from the Virchow-Krankenhaus (680/1928)—a case of partial appendicular mucocoele containing in its walls osseous foci showing a regular fibrillary structure.

Summary

A case of heterotopic ossification of an appendicular mucocoele is reported. Ossification was of wide extent and was associated with the appearance of haemopoietic tissue. The mucocoele had perforated and was accompanied by a gelatinous condition of the peritoneum. The various conditions required for the onset of ossification—structural, biochemical, and mechanical—were present and are discussed. The condition was not suspected clinically, being discovered only at operation.

Medical Memoranda

An Unusual Case of Large-Bowel Obstruction

The following case of large-bowel obstruction after perineal excision of the rectum merits recording on account of its rarity. A search of the literature failed to reveal a similar case.

CASE REPORT

A woman aged 54 was admitted to the wards of Mr R. A. Keane at the North Staffordshire Royal Infirmary on Nov. 27, 1946, complaining of pain in the centre of the abdomen for three days. She had vomited on the morning of admission. A perineal excision of the rectum had been performed nine years previously and the colostomy had functioned adequately till one year ago, when a plastic operation was carried out for stenosis of the opening. Thereafter the colostomy had again functioned normally until two days before admission. There had been no bowel action since. There was also difficulty in micturition.

On examination the temperature was 98° F. (36.7° C.), pulse 92. The tongue was furred. The abdomen was soft, and a large median swelling was visible in the suprapubic region which was tender and resonant on percussion. Normal bowel sounds were heard and there was no evidence of intestinal colic during examination. A left inguinal colostomy was present which looked quite normal, but it was impossible to introduce a finger into either opening.

Operation. Under general anaesthesia—nitrous oxide, oxygen, "trilene" and ether—a right paramedian subumbilical incision was made. A gangrenous mass of large bowel presented in the wound. This proved to be the blind efferent loop of large bowel leading from the colostomy. It was not fixed distally to the pelvic floor, but hung free in the pentoneal cavity as a pendulous sac. This sac was about 8 by 3 in. (20 by 7.5 cm.) in size, had undergone torsion at its base, and was bluish in colour. This blind end of colon was resected, leaving about a 14-in. (37.5-cm.) stump at the colostomy. Free blood-stained fluid was mopped out of the pelvis, revealing the uterus firmly attached to the sacrum by adhesions on its whole posterior surface. Sulphathiazole, 5 g., was inserted in the peritoneal cavity and the abdomen was closed with a stab drain to the pelvis. The colostomy acted profusely before the patient left the table. Examination of the specimen showed a black gangrenous mucosa; the sac of bowel contained a heavy, purty-like faecal mass about the size of an orange and with a most offensive odour. Convalescence was uneventful, and the patient was discharged home on the sixteenth day.

COMMENT

This unusual complication of perineal excision of the rectum could occur only where the distal segment of bowel was hanging free and was not fixed in the usual manner to the reconstituted pelvic floor. This and the adherence of the uterus to the sacrum suggest either that an inadequate repair of the pelvic peritoneum had been carried out or that it had broken down post-operatively. The weighty faecal mass was presumably a precipitating factor.

My thanks are due to Mr. R. A. Keane for permission to publish this case.

KENNETH G. F. MACKENZIE, M.B., F.R.C.S.,
Resident Surgical Officer,
North Staffordshire Royal Infirmary.

Reviews

DOCTOR POL

Nicolaus Pol Doctor 1494. By Max H. Fisch. With a Critical Text of his Guaiac Tract edited with a translation by Dorothy M. Schullian. (Pp. 244; illustrated. \$7.50.) New York: Published for the Cleveland Medical Library Association by Herbert Pochner, N.Y. 21.

The contents of a medical library of early date may furnish an interesting commentary upon the contemporary state of medical knowledge. Consequently, a library which was built up during the early years of the sixteenth century is of surprising interest, and as each item in the collection to which this book refers is marked by the signature "Nicolaus Pol Doctor 1494" there is no difficulty in identifying the volumes when they are found. The date, as we shall presently show, does not refer to the book on which it is inscribed. The books and manuscripts of Nicolaus Pol originally numbered some 1,300 items, and those which still exist are now widely scattered. The present account is based upon the Cleveland Collection, which has had the following curious history.

In 1907 a young antiquarian bookseller in Munich, Maurice Fünfhäusen, sold to Dr. E. C. Streeter, of Boston, a bundle of some thirty incunabula and sixteenth-century books, each bearing the inscription of Nicolaus Pol. Twenty years later, as head of Mages Brothers, he visited Boston and bought back the collection. Catalogued and placed on sale, it was acquired for the Cleveland Medical Library through the services of Harvey Cushing and his nephew Edward H. Cushing, and once more it crossed the Atlantic. In America it remains as one of the richest treasures of the Cleveland Library. There were already 13 of Pol's books in the Yale collection, and a search in various libraries of Europe revealed many more. At San Candido, in Tyrol, 133 volumes were found. Others came to light at Innsbruck University, and a few elsewhere, although many are still untraced.

In the meantime Dr. Max H. Fisch has rendered useful service by publishing a catalogue of Nicolaus Pol's library so far as it is known. The work is, however, much more than a mere catalogue of this fine medical library of Renaissance date. From the scanty data available he has been able to construct a brief biography of the man himself. The place and date of his birth are uncertain. Tyrol, about 1470, is a rough guess. But we do know that in 1487 he was appointed Court Pharmacist to Duke Sigismund at Innsbruck at the beggarly salary of twenty florins a year, and in 1495 he became physician to the Emperor Maximilian at a hundred florins a year. The documents ratifying this appointment is preserved at Innsbruck and is reproduced as Plate I in this work. The date 1494, appended to each of his signatures in his books, may possibly have been the year to which he started medical practice. Certainly he was in no position to buy many books then. Between 1513 and 1520 his doings are revealed in a number of letters between Pol and Veit Bild, a monk of Augsburg, who appears to have acted as Pol's agent in purchasing books. A number of books are mentioned in the letters, including those of the Spanish astrologer Ramon Lull. Twenty works by Lull are included in the present list. It seems probable that Pol was a member of the commission sent to Spain by Cardinal Lang in 1517 to study the native treatment of syphilis, and from this mission there emerged his tract *De Morbo Gallico*, written in 1519 and now reproduced in full in Latin and English (pp. 50-97). The excellent translation is the work of Dorothy M. Schullian. The discovery of peruvian wood, taken with a much reduced diet, was a valuable alternative to mercury, which killed and maimed. No doubt Pol passed from the service of Maximilian to that of Charles V; certainly he continued to practise at Innsbruck, and there he died in 1532.

The second half of the book contains a list of the known works of Pol, a list of the libraries and of their present location. Among the titles are notably Aesop's *Fables*, 14 works of the *Practica*, and 11 of Villanova's *Regimen of Salerno*. There are also some of the *Practica*, Bartholomaeus Anglicus's *De*

Pulsibus, John of Gaddesden's *Rosa Anglica*, Guy de Chauliac's *Chirurgia*, Sir Thomas More's *Utopia*—one is tempted to continue, for the very names have a fascination, but the variety already obvious. It is a catalogue most attractive to the bibliophile. Four of the lovely bindings are reproduced as plate and there are excellent portraits of Maximilian, Cardinal Lang and Jacob Fugger. Other plates depict the guaiacum plant and its preparation as explained in Pol's book, as also in the more famous tract of Ulrich von Hutten. Unfortunately there is no portrait of Nicolaus Pol, who, to judge from his library, must have been one of the leading medical scholars of his time. This beautiful book reflects high credit on author and publisher alike.

DOUGLAS GUTHRIE.

GUIDE FOR STUDENTS

Symptoms and Signs in Clinical Medicine. An Introduction to Medical Diagnosis. By E. Noble Chamberlain, M.D., M.Sc., F.R.C.P. Fourth edition. (Pp. 464; 346 figures, of which 19 are in colour. 30s.) Bristol: John Wright and Sons. 1947.

The bewilderment of the first few weeks in the medical ward is an emotion so intense that most medical men can recall it for years afterwards. It may be that the introductory course now ordained by the General Medical Council prepare the clerk for his ordeal, but the need for some elementary written guide remains. Dr. Noble Chamberlain's book is designed to meet this need, and a measure of his success is given by its having passed through four editions and five reprintings in less than twelve years. Such popularity suggests that the book provides the student with what he believes he needs and forestalls criticism.

There are difficulties in reviewing a book addressed to a group of which the reviewer is not a member, for all teachers must hold their own views on what the student starting medicine should be taught. These views may differ not only from those of other teachers, but also from those of the student himself. Dr. Chamberlain's approach is conventional and unexceptionable, but the danger of this method is of reducing the patient to a disarticulated collection of systems and organs. Man would consider to be inadequate his definition of diagnosis as implying "knowledge of the organs or tissues affected by disease, and of the pathological changes which have taken place in them." His introductory chapter might with advantage stress the importance of the patient as an individual and a biological unit in the social structure. These are aspects which the student appreciates only when he is plunged into practice and finds himself no longer surrounded by "cases of mitral stenosis" but by sick people. The descriptions of methods of examination and of physical signs are excellent, and most of the half-tone illustrations apposite and well produced; some of the colour plates are less successful. This edition will continue to guide the student satisfactorily through the maze of his first period in the medical wards.

R. BODLEY SCOTT.

NURSING OF CHILDREN

Textbook on the Nursing and Diseases of Sick Children for Nurses. By various authors. Edited by Alan Moncrieff, M.D., F.R.C.P. Fourth edition. (Pp. 744; 154 illustrations. 30s.) London: H. K. Lewis and Co. 1947.

The new edition of this excellent book on the nursing and care of sick children is larger by 100 pages and has a number of new illustrations; one, or two contributors have been changed, but it has been thoroughly revised; but it is substantially the same book, and bears on every chapter the authoritative stamp of Great Ormond Street. Although the book is well known and established, it deserves something more than a brief notice of commendation. Its purpose is to serve as a manual for student nurses training in children's hospitals and to prepare them for the examinations necessary for entry on the State Register of Children's Nurses. Its excellence is partly, perhaps largely, due to the happy combination of the medical, surgical, and nursing staff of Great Ormond Street Hospital in planning and writing it. In the preface we come across the phrase "scientific

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY MAY 15 1948

WHAT WE HAVE GAINED

The statement by the Council drawn up at the end of its last meeting on May 5 after consideration of the results of the plebiscite was printed on a loose sheet which was inserted into last week's *Journal*. As the number of general practitioners voting No in answer to Question B was far short of the 13,000 required if collective opposition to the Act was to be continued, the Council is recommending the Representative Body to be prepared "to co-operate in the new service on the understanding that the Minister will continue negotiations on outstanding matters, including terms and conditions of service for consultants and specialists, general practitioners, public health officers, and others." The Council also resolved to accept the Minister of Health's invitation to enter immediately into discussions on the details of the promised Amending Bill, and on other outstanding matters. The Council's decision has been widely hailed by the Press as wise and statesmanlike. That this decision was right finds support in the correspondence columns from that Nestor of medical opinion, Dr. Alfred Cox, who was Medical Secretary of the B.M.A. in 1911 and retired after long years of service in 1932. His views, we believe, will carry great weight with the representatives who are to attend the Special Meeting on May 28. "Our best policy," Dr. Cox believes, "is to accept the verdict of the plebiscite ungrudgingly and to urge those doctors who join the Service that they will receive the whole-hearted support of the Association in making the Service a credit to the profession." He recalls the famous observation made by the *Westminster Gazette* in 1912 and refers to the comment made in the *Economist* about a fortnight ago. "Undoubtedly the doctors have won a big victory, for Mr. Bevan does not easily climb down to the extent that he has done."

Some correspondents have taken this *Journal* to task because of the content and tone of the leading articles that have appeared since Mr. Bevan's statement in the House of Commons on April 7. We avoided using the words of the *Economist* because it seemed ungracious to crow over Mr. Bevan when he made a generous gesture in unexceptionable terms. But our critics seem not to have realized that the situation has changed since December of last year, and indeed, since the time when Mr. Ernest Brown, Liberal National Minister of Health in the Coalition Government, put forward his proposals for a health service in 1943. We may recall that the Coalition Government proposed that general practice should be carried on by a health service, manned by whole-time full-salaried doctors, and that the right to private practice. The young doctors would enter this service at a salary of £400 a year, and the bulk of the 46 would not ordinarily

be earning more than £1,200 a year. We have only to contrast the scheme put forward by a Liberal Minister of Health with the present scheme to see what great changes have been made as a result of the intermittent negotiations that have been going on for the past five years. The Central Medical Board in Mr. Brown's and in Mr. Willink's scheme had wide powers over the general practitioner, including the power of appointment. The first move away from this situation was to devolve on Local Executive Councils with full professional representation the principal responsibility for selecting men for vacancies in general practice. Mr. Bevan has now finally devolved this responsibility where it should properly lie—the general practitioner himself, who has the right to choose his partners and assistants. Mr. Bevan, too, has accepted the Spens Committee recommendations on remuneration for general practitioners, which go far beyond the mean proposals of Mr. Ernest Brown.

When Mr. Ernest Brown and Mr. Willink were Ministers of Health the B.M.A. strongly opposed the idea that the new health service should be administered by local authorities. There was particular objection to the municipal control of hospitals, and as an alternative it was advocated that they should be administered in regions based on universities. The opposition was so effective that the municipalization of the hospital service was abandoned and the regional idea was accepted. Mr. Brown would have allowed in his scheme no private practice to the general practitioner. The B.M.A. successfully resisted this, and Mr. Bevan in his Act has granted the right to private practice to general practitioners and to consultants and specialists. Free choice of doctor being incompatible with a full-salaried service, the B.M.A. won its point that payment should be principally by capitation fee, and Mr. Bevan now has removed the objectionable feature of the universal basic salary, which many people with reason saw as an attempt to control certification. When the Negotiating Committee met Mr. Bevan in December of last year it presented a fully argued case on the ambiguities of Sections 35 and 36 of the Act. Mr. Bevan then took no notice of these objections, but has since set up a legal committee to inquire into them with the promise of amendment in the terms of the legal committee's findings. Another point pressed upon Mr. Bevan was that health centres should be the subject of experiment. Mr. Bevan, though pressed on by the Socialist Medical Association and its supporters, has refused to be hurried in the matter of health centres. In the first place, building materials and labour will be more usefully employed in providing new houses, and in the second place he has agreed with the B.M.A. view that further inquiry is needed. Mr. Bevan has met the professional demand for free expression of opinion on all aspects of the Service, and will put in the contract an assurance that this will be safeguarded. He has, too, promised to submit Regulations in draft to the B.M.A. Although he retains his power of negative direction, he has restricted this by agreeing that any doctor should practise where he likes in those areas not defined as being over-doctored. In fact, when we review the situation as it has evolved since the first plans of the Coalition Government were made known, it

is clear that the medical profession has by its tenacity in negotiation made very considerable gains. There was a fear in the early months after the publication of the Beveridge Report that the Government would introduce only the medical part of its social security plan, and the B.M.A. stated¹ that it would co-operate with the Government if Parliament "decided to accept the assumptions of the Report and to put into operation the proposals of the Report, taken as a whole. . . ." The conditions of co-operation have been fulfilled.

The medical profession has not succeeded in persuading Mr. Bevan to grant the right of appeal against the decision of a tribunal of the Minister to remove a man from the Service. It has failed to persuade the Minister to remove his power of negative direction, and it has failed to remove from the Act the prohibition against buying and selling public practices. This last point is one of much importance to general practitioners. But Dr. Cox has put the matter in a nutshell when he writes: "To continue to oppose the working of the Service because we have failed on the goodwill issue would be to fly in the face of what is possible." In addition to the reasons he gives to support this statement there is the fourth and compelling reason of the economic position of the young man entering general practice to-day. The ownership of goodwill was a defence against a full-salaried service and also gave to the owner the right to choose his partner or assistant. Mr. Bevan, by his own decision, has made the introduction of a full-salaried service under the present Act impossible, and he has restored to the general practitioner the right to choose his own partner and assistant.

It would seem that some of our correspondents do not have a "whole-hearted desire," or, indeed, any desire at all, for a comprehensive medical service available to the whole community. This is a tenable position, but it is not the policy of the British Medical Association. The Representative Body has accepted a service available to 100% of the community. Valid arguments can be brought against the inclusion of the whole population in a National Health Service, but again the exclusion from such a service of 10% or 15% of the population is not B.M.A. policy. We recall the observations made by Dr. H. Guy Dain, the Chairman of Council, at the Special Representative Meeting two years ago.² As reported, he said "that in his view the question of proceeding to get anything less than 100% was dead. Their opponents would be delighted to see them come out and claim that the Service should be for less than 100%. He would not say that he was in favour of 100%, but he had never seen any method of dividing the population for a complete medical service, though it might be done with the present restricted N.H.I. service." Through its representative organization the medical profession has since the publication of the Beveridge Report reiterated its desire for the comprehensive medical service available to the whole community that was the fulfilment of Beveridge's Assumption B. A succession of Ministers of Health have yielded ground in the face of the B.M.A.'s sustained opposition to certain of their proposals. Mr. Bevan, in the light of his own statements and of the

policy of his own Party, has by his promise of an Amending Bill and other concessions in written answers to questions gone a considerable way to meeting the demands of the medical profession. He has offered a compromise, and compromises are the traditional English way of settling disputes. For the medical profession to reject the compromise and to be intransigent would cost it the support of public opinion. The B.M.A. Council, viewing the situation as a whole, has made what is widely acclaimed as a wise decision in recommending the Representative Body to co-operate with the Government in launching the new service. Much remains to be done, and the profession's negotiators will need its support and trust in moulding the new service through the vigilant oversight of Regulations and in securing satisfactory terms and conditions. During the past months the medical profession has shown its strength and has shown, too, that it can use it with wisdom.

WAR AND MEDICAL RESEARCH

The Medical Research Council has performed a useful service in bringing together in the shape of a Command Paper an account of the manifold work which was done under its auspices during the war. Those who live during a period of great events seldom appreciate the magnitude of such events until later when the opportunity arises to see them in retrospect. Every month or every week during the years of the war seemed to bring to the fore some outstanding piece of medical investigation in one or other field, but it is only when these investigations are described in a connected narrative that we are able to realize how numerous they were, what an enormous field of inquiry they covered, what an army of experts was enlisted, and how decisive many of the results were in the conquest of disease, in the protection of those exposed to unusual hazard and in the rehabilitation of those who had suffered wounding or other injury.

The pace of medical science is accelerated in wartime. The slow-growing plant of medical research undergoes a forcing process. This is due in large measure to national urgencies, requiring instant solutions of problems which otherwise would have been attacked more leisurely. But there is another reason why medicine, both medical research and medical service in general, makes advances during war. War is a challenge to medicine. Medicine is concerned with the saving of the individual life and the reduction of suffering. With the outbreak of war the nations concerned are delivered over to destructive forces with which the single life counts as nothing at all. The impulse to go forward with medical work of any kind is due in part to the desire to fortify threatened ideals and to save something for sanity in a mad world. Yet by a strange irony medicine itself contributes enormously to the very effectiveness of the war machine. It enables men to sustain the struggle as they never would if the resources of medicine were not available, and even when they fall wounded it restores and re-equips them so that often they can go into the fighting line again. In the campaign in North-Western Europe in 1944-5 it was estimated that if the British soldier wounded in the field of battle came into

¹ *British Medical Journal*, 1943, 1, 193.

² *British Medical Journal Supplement*, 1946, 1, 133.

the hands of the medical service the chance of his survival was about 93% and of his recovery to a degree fitting him for a reasonably wide range of employment 84%. Until the final stage of atomic bomb devastation it could be said that advances in methods of destruction had been matched by advances in saving life. Thus medicine may be said to prolong and intensify the combat. It can even force military decisions. The effective introduction of malaria suppression by mepacrine was decisive in the overthrow of Japan, as it permitted military operations to be conducted successfully whereas otherwise they would have been impossible.

Much of the work described in the Medical Research Council report, reviewed on other pages, will be familiar to our readers owing to the fact that during the war years there was constant publication. Only a very partial censorship descended upon medical achievements. This is shown by the fact that there are not far short of two hundred references to wartime papers published in the *British Medical Journal* alone.

The report surveys the work done on the treatment of wounds and injuries and of war diseases, the work on nutrition, the investigations which come under the term "personnel research," the emergency services, such as those concerned with immunological supplies and with blood transfusion, the preparation and maintenance of biological standards, and much more. A great deal of the work done, such as the organization of a public health laboratory service, remains as a legacy bequeathed by war to peace. One golden thread runs through all the narratives. Those engaged in medical research of one sort or another not only have their outstanding abilities and often uncommon genius to the national effort but served with a personal devotion, a courage, and a sacrifice in their laboratories or wherever it might be, worthy of the similar qualities shown by the men in the fighting Forces. Those concerned at the National Institute for Medical Research, for example, were studying the physiological effects of high oxygen tension, which meant entering a pressure chamber; 300 such "dives" were taken with a fine disregard of personal distress. At the same centre the problem of protection against flame was being studied and tests on certain skin paste called for a high degree of personal courage. So with the experiments on "climatic physiology" carried out in "hot rooms" at the Admiralty, involving a tremendous strain on those concerned, with frequent heat collapse and stamps. Soon after the outbreak of the war, when it was evident that rationing on a scale to which the British people had never been accustomed would have to be enforced, the two members of the staff of the Department of Experimental Medicine at Cambridge intimated that they and certain attached workers were prepared, in advance of compulsory rationing, to subsist voluntarily for a period of six weeks on a very restricted dietary scale, suddenly imposed in order to observe its physiological and psychological effects on the health of adults of both sexes. Their diet was planned to correspond exactly with those of the troops to be expected to be available for the general population under very severe blockade conditions. The diet which these workers accepted was more severe than that which was afterwards proved to be necessary, but

their experiment materially influenced subsequent policy concerning food rationing. Another example was afforded by the twenty volunteers—conscientious objectors to military service—who served as subjects for experimental transmission of scabies and who later collaborated in important dietetic experiments, subsisting on a diet as deficient as possible in vitamin A and carotene. There were also volunteers who underwent experimental infection with jaundice in pursuit of the investigation of infective hepatitis. Some of these were rheumatoid arthritis patients who hoped that an attack of jaundice might relieve their condition—as it did temporarily—but others were inspired by the pure zeal of the investigator.

The report includes an extended tribute to three distinguished men in medical research, two of whom died during the war (Sir Patrick Laidlaw and Sir Thomas Lewis) and the third (Sir Henry Dale, O.M.) retired from the service of the Council after being a member of the staff for twenty-eight years. It is considered worthy of note at a time when the question of attracting the best brains to scientific work in the Government service is being much debated and reported upon that three such men as Laidlaw, Lewis, and Dale, of the highest international fame in medical research, should have given their best years, with an average period of a quarter of a century, to the service of the Medical Research Council.

THE MYSTERY OF THE EOSINOPHIL

An increase in circulating eosinophils is a feature of a number of disorders which otherwise appear to have little in common. There are groups of conditions, such as allergic diseases of all kinds, parasitic infestations, and cutaneous eruptions, in which we can at least say that sensitization, a metazoan parasite, or a visible skin disease links the group together. But outside these categories come a number of other conditions which appear to have nothing to do with the three main groups. One of these is lymphadenoma: enlargement of lymph glands with eosinophilia nearly always leads to the diagnosis of that disease. The eosinophilia may be very marked indeed and extend to 50% or more of the total leucocytes, themselves abnormally increased. Some have felt that this implies an allergic background, and attempts, apparently unsuccessful, have been made to prove sensitization by intradermal inoculation of lymphadenomatous material. It is probable that in this disease the eosinophilia in the blood is the result of an overflow from the eosinophil deposits in the affected lymph glands, and that it is therefore analogous to the lymphocytosis in lymphatic leukaemia. Eosinophilic leukaemia may be considered as a disorder linking the true leukaemias and lymphadenoma, and lymphadenoma should be looked upon as one of many possible forms of malignancy in an organ with many functions and an eventful embryonic career.

Sometimes, however, eosinophilia with enlargement of lymph glands occurs in serum sickness and may be confusing. The presence of heterophilic antibodies to sheep cells differentiates the two conditions—the test for these is so unpredictable and apparently irrational that it recalls some of the methods of mediaeval medicine in its more esoteric phases.

Allergic eosinophilia is most variable in its appearance. Many patients with severe asthma have no eosinophilia; on the other hand, there may be marked eosinophilia in patients who react acutely for the first time to certain drugs or foodstuffs.

Symptomless eosinophilia is most often due to metazoan parasites, and in certain parts of the world where helminth infestation is universal eosinophilia is equally common. In the tropical belt of Africa infestation by *Filaria perstans* is both symptomless and practically universal, at least in some areas, and the eosinophils may amount to 70% or more of the circulating leucocytes. It should be remembered that amocbiasis does not cause eosinophilia—protozoa never evoke a response which is essentially metazoan. For some time to come helminth infestation must continue to be carefully excluded in adult males with eosinophilia, particularly in those who, interned in Japanese prison camps, so commonly contracted hookworm and *Strongyloides* infestation.

A further condition commonly associated with eosinophilia is periarteritis nodosa. This disease is to-day recognized to be more common than was once believed, and a proportion of the cases recover. Unless a biopsy is possible on a skin nodule the diagnosis of the condition must always be a guess; but eosinophilia is commonly encountered, and where albuminuria, fever, and eosinophilia are found together this disease must at least be considered. The contemporary view is that the condition is allergic, and the eosinophilia certainly gives this some support.

Of recent years there have been separated certain other conditions, all rare, in which eosinophilia is present in tissues or circulating blood and where some authorities have thought it possible to define clinical entities. One such condition is eosinophilic granuloma of skin, detailed studies of which have recently been published.¹ Clinically the disease is stated to be a chronic and usually self-limited condition in which doughy, firm, reddish-brown tumours form in the skin. The diagnosis is essentially a laboratory one, since eosinophilia of the order of 50% is present in the circulating blood and also in the actual lesions. The condition is strikingly similar histologically to periarteritis nodosa, since the lesions occur in relation to small blood vessels and perivascular tissue. Allergy has also been confirmed in some cases; for example, a *Trichophyton* was grown from the feet of a patient, and trichophytin extracts gave positive intradermal reactions.

A much-disputed eosinophilic disorder of the lungs was described by Löffler² in 1932, and a similar condition, commonest apparently in India, is known as "tropical" eosinophilia. A survey of the latter condition has recently been made by Joseph,³ who considers the two disorders distinct. But in certain cases such as that described by Perlingiero and György⁴ infestation with roundworms has been present. Indeed, so many types of worms pass through the lungs at one stage of their life cycle that pulmonary symptoms due to their presence are inevitable. Very definite proof that a parasitic infestation is absent must be demanded before

accepting these disorders as new entities. The discovery of mites in the sputum of patients must be accepted with abundant reserve. Entomologists tell us that their peace of mind is constantly being undermined by reports of mites in sputum, urine, or faeces. The truth is that mites are everywhere and easily fall into containers later filled with pathological material.

Eosinophilic granuloma of bone is a much more distinct entity. It was first described by Finzi⁵ in 1929, and something under fifty cases have been recorded. It is now generally agreed that the condition is one stage in the development of a disturbance of lipid metabolism, and that the clumsily named Hand-Schüller-Christian disease is essentially the same disorder at an earlier stage. Other conditions in which tissue or blood eosinophilia may be present are numerous, but in most of them the eosinophilia is erratic and of most uncertain significance. In the whole gastro-intestinal tract, for example, acute inflammation is often eosinophilic; in widespread secondary malignant deposits blood eosinophilia has been recorded, but is not the rule; eosinophilia in blood and tissues occurs in some cases of radium sickness; and on occasion eosinophilic pleural effusions are found which appear to have no common aetiology or prognostic significance.

There is, in fact, no apparent link between all the varied conditions in which eosinophils are a prominent feature. But it is worth remembering that ignorance about the function of all other leucocytes, except the polymorph, is as great. No one has suggested what function a basophil cell or a monocyte may be expected to carry out. Lymphocytes amount to 40% of circulating cells, yet few haematologists would like to be dogmatic about their purpose. If the eosinophil is a mystery, it is at least in good company.

POLICY FOR PEOPLES

The relatively high birth rate in this country in 1946 and 1947 has silenced temporarily the talk of a persistent and cumulative decline in population. Not long ago the view was put forward that the population of Great Britain might well be declining by a quarter or more in each generation before the next half-century was out. It was even predicted that by 1948 there would be some fall in total numbers: this has not occurred, and a large decline seems now more remote. Predictions in this field, of course, cannot be much better than guesses. This is borne out by a table which appears in a report on *Population Policy in Great Britain* just published by P E P (Political and Economic Planning).¹ Five different assumptions are made regarding mortality and fertility trends in England and Wales during the next hundred years. If we take the most pessimistic of them it leaves us with a population at the end of that time of something like 14 millions, and if we take the most optimistic we have a population in the 'forties of the next century of 43 millions, which is very much what it is at present. According to the results of some research at Princeton University the population of the British Isles may have fallen by 1970 from something over 50 millions to under 47, while that of Soviet Russia (its pre-war territories

only it will have risen from 174 to 222. These are interesting exercises in what the statisticians call "projection," but the unknown factors are so many that the results must be subject to heavy discounts.

During the recent war there was a relatively high level of fertility in this country. The "baby slump" of the 1914-18 war was not repeated. In the Netherlands during the year after liberation the birth rate was higher than ever before in their history; in France it was the highest for a quarter of a century, and it rose even in Germany. Evidently if there is a "retreat from parenthood" it is not an orderly and continuous retreat; there are hesitations and retracings. Nevertheless, the practice of family limitation has spread gradually from groups of the highest social standing to all classes of the population in this country and in a large part of western Europe. With wider opportunities for advice on birth control a fall in the birth rate is only to be expected, though with relatively fewer people dying a decline in population can be temporarily avoided. For a time birth control and death control may keep in step. But the childless marriage and the one-child marriage will be more frequent; there will be fewer unwanted children and fewer intentional abortions; and if it should come about that all parenthood is voluntary so much the better both for parents and offspring, but without some policy at national level the numbers of the population may fall catastrophically.

The term "population policy" would have scandalized our forebears, who took bitter exception even to Malthus's well-intentioned proposals for postponed marriage, not to speak of the neo-Malthusian advocacy of control of fertility by contraception. There are individualists who maintain that no attempt should be made to influence people's reproductive behaviour. Authoritarian banning of non-injurious contraceptives is now out of the question, and mere exhortation to people to have more children is futile. A population "drive" would cover itself with ridicule. Parliament cannot deal with the unborn generations as it deals with the gas industry or with doctors. But a population policy directed to the encouragement of parenthood can be pursued in ways which are very ably set forth in this P E P report. One measure is obviously financial assistance to parents by means of maternity grants, family allowances—the present family allowances, in the opinion of P E P, should be doubled—social insurance, and tax rebates. These of course should be accompanied by the provision of suitable houses and other environmental health services. A case might also be made out for low-interest marriage loans. These measures for the encouragement of parenthood which are already in being to a greater or less extent, can be advocated on grounds of social justice apart from their effect on prospective population; but, as someone has remarked before, if children are not had for love they are likely to be had for money. Over and above all this there is something imponderable—the raising of the birth rate in this line. A large family was once the subject of respect; later it became a subject of jest, and even of scorn, and the ground of imprudence. There are signs, however, that the bringing up of children is enjoying a new respect. His Pers. Mr. Quigley is now a more

The principal proposal in the P E P report hinges on the National Health Service, from which P E P expects a great deal. The Service, it says, provides the setting for a revolutionary advance in personal health care of the individual and family. It even gives the Minister of Health the additional portfolio of Minister of Population. Within the National Health Service it desires to see a Family Welfare Service in which the general practitioner, fortified perhaps by a code of practice prepared by the British Medical Association, will be the pre-marital adviser. Well, we pause there. It is admitted at once, of course, that the health of the parties is an important element in conjugal success, but it is not the only element, and to make the general practitioner apparently the sole marriage counsellor argues too wide a view of the practitioner's functions and too restricted a view of marriage. If there is to be a recognized system of marriage guidance it will require not one counsellor but a whole board—doctor, priest, eugenicist, economist, and perhaps several others, including, for the present at any rate, a house agent. Compulsory pre-marital medical examination, as one would expect, finds no acceptance. Apart from other objections, it would raise in an acute form the question of professional secrecy.

On the difficult matters of contraception and abortion P E P has much to say. It is of opinion that local authority clinics should not be limited to giving contraceptive advice to married women on medical grounds only, and that in principle such advice should be freely available, though it acknowledges that doctors in dealing with unmarried women may have to make exceptions in particular cases. In giving contraceptive advice generally doctors will help to foster the new attitude to parenthood without which a positive population policy based on democratic principles is bound to fail. As for abortion, the Interdepartmental Committee took the view that induced abortion could be justified for one reason only, to protect the woman's physical and mental health. The compilers of this report hold that the case for legalized induction, with the woman's consent, on certain eugenic grounds, especially of course having to do with mental defect, is very strong; but safeguards are necessary to prevent too wide an interpretation of "eugenic grounds." The most radical approach would be to make abortion available to every woman who desired it, provided there were no medical objections to the operation. It is recognized, however, that religious, ethical, and practical objections to the general legalization of abortion are much stronger than the objections to contraception. Contraception, unlike abortion, does not involve the actual destruction of human life.

This and other aspects of the population question must await further advances in medical knowledge and the crystallization of public opinion. The Minister of Health has recently stated in Parliament that the long-awaited report of the Royal Commission on Population may be completed this year, and it will be interesting to compare this with the P E P report. The latter can be commended for not losing sight of quality in pursuit of numbers, and for pleading not only for larger families but for a new attitude towards the family which should govern all discussion of social reform.

ACUTE PORPHYRIA

Failure to diagnose acute porphyria may lead to an unnecessary laparotomy in a seriously ill patient, and this undesirable error can be avoided only if the disease is considered as a possibility in the differential diagnosis of acute abdominal pain. Sudden onset of pain, with vomiting, constipation, and pronounced tachycardia, strongly suggests a surgical or gynaecological emergency (the patient is often a woman), especially when accompanied by guarding or rigidity in the lower quadrants of the abdomen, but when these signs and symptoms are due to acute porphyria doubt about the precise cause will usually arise. Abrahams, Gavey, and MacLagan¹ have observed that a urinary infection may also confuse the diagnosis. Elsewhere in this issue Dr. E. Petrie describes a case of acute porphyria and draws attention in his introductory remarks to the paucity of reports in British medical literature about this condition, which probably occurs more frequently than is generally realized.

The diagnosis can be firmly established only by examination of the urine, the appearance of which may be misleading in that the characteristic darkening to a port-wine colour does not appear if the urine is alkaline. Attacks frequently begin at the time of the menses, and coloration could be ascribed to contamination,² an error that may be increased by confusion between the absorption bands of haemoglobin and the zinc complex of porphyrin, which is probably the form in which porphyrin is always present in the urine in these cases. Provided due regard is paid to its distinction from urobilinogen, which may also be present, as Discombe and D'Silva³ and others have found, the reaction of the urine with *p*-dimethylaminobenzaldehyde is apparently pathognomonic of the condition.³

Dr. Petrie's case is another example of the usual sequence of events which, curiously, are so "remarkably stereotyped." Symptoms and signs of central nervous involvement were present, with emphasis on the loss of motor function. In view of the fact that in affected individuals the condition is latent between attacks, or in others it may remain latent, it is obviously important to prevent them from taking drugs widely held to precipitate attacks. The drugs most incriminated are the barbiturates, sulphonal, and "trional." Hence the sedation of these patients, especially during the often-encountered phase of respiratory weakness, may become a difficult problem. Other substances also under suspicion are sulphonamides,⁴ alcohol,⁵ and lead, which sometimes all produce type III coproporphyrinuria in normal individuals. Recently Brunsting and Mason,⁶ working at the Mayo Clinic, have made a careful study of four patients, all alcoholics, with hepatic impairment and lesions of the skin. Although the aetiology of this condition is obscure, the observations of these workers may lend support to the view, re-emphasized by Prunty⁷ and based on other evidence, that the disease might be one of disordered hepatic metabolism. Other recent studies have raised doubt whether Waldenström's uroporphyrin III, found in this condition and held to be typical of acute porphyria, is in fact a chemical entity and not largely composed of uroporphyrin I.⁸ This would be more in accord with the increasing number of reports of cases from the United States which combine features of both acute and congenital porphyria. Both conditions can

still be regarded only as "inborn errors of metabolism," and elucidation of the nature of the errors still requires considerable biochemical investigation.

NEUROMUSCULAR SYSTEM IN RHEUMATOID ARTHRITIS

The peripheral nerve symptoms in rheumatoid arthritis—muscle weakness and atrophy, numbness and paraesthesiae, and trophic changes in the skin—are features of the disease which led at one time to the belief that it originated in the central nervous system. This gave place to the view that an infection attacked the joints and that the other symptoms were secondary to this. Of recent years further research has shown that the joint symptoms are part of a general systemic disease and not the primary lesion. As far back as 1903 Llewellyn Jones¹ noticed that disturbed muscle function frequently preceded local evidence of joint disease, and this observation has received strong support from the demonstration by Steiner *et al.*² in the U.S.A., and by Gibson, Kersley, and Desmarais³ in this country, of local accumulations of cells in the nerve sheaths and the interstitial tissue of the skeletal muscles. In the neighbourhood of these small and scattered lesions local degenerative changes affecting the axons and medullary sheaths of the nerves can be seen, and there is often extreme thinning of the muscle fibres accompanied by increase in the interstitial connective tissue.

Morrison, Short, Ludwig, and Schwab,⁴ of the Harvard Medical School, have made an extensive investigation of the neuromuscular system in rheumatoid arthritis, using electro-myographic tracings and histological studies in a group of patients with well-marked rheumatoid arthritis. Patients with other forms of joint and muscle disease as well as healthy individuals formed a control series. They found no specific lesions in the central nervous system, but more pronounced alterations of the kind attributed to ageing than in controls of the same age. These changes were seen chiefly in the lateral projections of the anterior horns. Lesions were found in the peripheral nerves in 26 out of 31 cases and in the muscles in 8 out of 14 cases, thus confirming the findings of previous observers. Following careful research for involuntary muscle activity, fibrillation or fasciculation, spasticity, spread of tendon reflexes, voluntary and reflex muscle contractions, and neuromuscular influences in general, these workers concluded that lesions of the lower motor neurones were responsible for the muscle changes and neurological signs. Retrograde degenerative changes were found in the posterior root ganglia in several cases, confirming the observations of Penny⁵ in 1913. In a very interesting case of arthritis affecting only one side certain reactions were noted in the forearm muscles of the opposite side, the joints then uninvolved. The following week the patient developed pain and arthritic signs in the unaffected hand—a very suggestive sequence of events.

ACCOMMODATION AT ANNUAL MEETING

The accommodation at Cambridge for the Annual Meeting of the B.M.A. is limited. In order that the arrangements may run smoothly we would ask those who intend being present to notify the Executive Officer as soon as possible. The form for doing so appears at p. 123 of the Supplement this week.

MEDICINE IN THE 1939-45 WAR

REPORT OF MEDICAL RESEARCH COUNCIL

The Medical Research Council has gathered into a report running to 450 pages a brief account of the many-sided research which it sponsored or otherwise assisted during the war. A vast amount of actual research was promoted by the Council, much of it with the object of supplying quick answers to newly emerged and urgent problems; it advised Government Departments and the Services on the application of scientific knowledge in the medical field, and it was responsible for many administrative tasks which a scientific organization was best fitted to carry out. Medical research in the war had three objects: (1) to maintain the health of the Armed Forces and civil population, particularly by the prevention of infective diseases and malnutrition; (2) to advance all methods for rapid restoration of wounded and sick; and (3) to elucidate the conditions required for the highest possible efficiency of fighting personnel and industrial workers. The Council worked through 44 committees, in which advisers and experts of the greatest experience and ability were employed.

On almost every page of this report the reader will feel that he has read the same thing before. The bibliographies appended to the various sections make it seem that almost everything brought forward has already been the subject of a special publication or of a paper in a medical journal. The hand of the censor certainly did not lay heavy here. During the war 24 special reports of the Medical Research Council were issued; in addition there were 17 war memoranda, presenting a concise summary of current knowledge on subjects of urgent practical importance under war conditions. Innumerable papers were published from the National Institute for Medical Research and from the Council's external research establishments, over twenty in number. In the bibliographies in the report we find references to no fewer than 174 papers published during the war in the *British Medical Journal* alone, and there are many others in our more specialized contemporary journals.

One of the Council's achievements was the *Bulletin of War Medicine* in 60 parts from September, 1940, to August, 1946, which formed an international exchange of medical information especially for Service medical officers cut off from direct access to original publications. The traditions of this wartime *Bulletin* are being maintained on an expanded basis by the new monthly abstracting journals brought out in the editorial department of the *British Medical Journal*.

Most of what appears in this report will be familiar, but it is useful to have it brought within a pair of covers in a readable and well-documented form. The following summary will remind readers of how much was done for medicine in this country by the Medical Research Council under the guidance of its executive, Sir Edward Mellanby.

Wounds and Injuries

A War Wounds Committee was appointed by the Council during the campaign in Flanders and France in 1940, when, owing to the speed of the enemy's advance westward, large numbers of wounded had to be transferred to Britain before adequate surgical attention could be given to their injuries. The very large expert committee, with six subcommittees concerned respectively with anaerobic wound infections, burns, chemical and crush injuries, vascular injuries, and pathological changes, worked under the chairmanship of the late Sir Charles Wallace and later under that of Sir Ernest Rock. Among its first acts was the publication of a pamphlet on the prevention and treatment of gas gangrene and the control of the production of toxoids for the active immunization of troops against the more important clostridia of the disease. Gas gangrene, however, proved to be one of the least serious forms of wound infection, important only because of the danger it involved to life and because of the need of the prevention and treatment of other types of wound infection which was much wider in its scope and

was attended by a very much higher degree of clinical success. The report reviews the development of wound treatment during the war, as exemplified particularly by the treatment of limb wounds in the British Army, and then summarizes current opinions of the uses and limitations of the sulphonamides and penicillin in the prevention and treatment of wound infection.

The following is given as a fair summary of current views on this last subject:

(1) Sulphonamide drugs, applied locally or given systemically (or both), are of only limited value in restraining the development of local infection in wounds; but are of definite value in preventing the systemic spread of streptococcal infection from a local focus such as a wound or burn. Both penicillin and the sulphonamides are effective in treating such systemic streptococcal infections on the rare occasions when these occur.

(2) The local use of sulphonamides will control infection by susceptible bacteria in superficial wounds; in deeper wounds these drugs, however administered, often fail to prevent or cure a local infection. The sulphonamides, used locally, are of value in preparing superficial wounds or burns for early skin-grafting, and penicillin, used locally, systemically, or both, is still better for this purpose.

(3) Penicillin has some outstanding advantages over the sulphonamides; it is effective against a wider range of Gram-positive bacteria; it is not antagonized by the presence of pus, it can be given systemically in large doses without serious danger of toxic effects, and it can be injected locally with less risk into body cavities. One of its comparative disadvantages is that it cannot economically be given by mouth. The combined use of penicillin injections and of sulphonamides by mouth has not been shown to give better prophylactic results against wound infection than the use of penicillin injections alone.

(4) Neither penicillin nor sulphonamide prophylaxis is a substitute for early and efficient primary surgical treatment of the wounded, but penicillin is a very valuable adjunct to surgery.

(5) Neither penicillin nor the sulphonamides will prevent the occasional development of gas gangrene in limbs deprived by injury of their blood supply and containing damaged and ischaemic muscle tissue.

(6) Neither penicillin nor sulphonamide therapy is effective against the Gram-negative bacteria which may infect wounds or burns at a relatively late stage (the stage of sloughing). For these cases alternative methods of treatment are necessary, of which irrigation with sodium hypochlorite solution is probably among the best at present available.

The report reviews the studies on hospital cross-infection, emergency amputations, and war fractures.

Burns, Brain and Nerve Injuries, etc.

A wide programme of research on the pathology and treatment of burns was sponsored by the Council during the war, and it soon became apparent that the problems of burns and their systemic effects were so manifold and complicated that an intensive system of co-ordinated laboratory and clinical research was required. Special reference is made to the experimental investigations in Prof. R. A. Peters's department at Oxford on "burns toxæmia" and the metabolic effects of burns; also to the work of the Burns Research Unit at Glasgow Royal Infirmary which led to the development of a first-aid cream containing penicillin and a sulphonamide drug for the elimination of streptococci. This preparation—"Glasgow No. 9 Cream," as it was called—was widely adopted for the treatment of Service and civilian casualties.

The Brain Injuries Committee, under the chairmanship of Prof. E. D. Adrian, examined the problems of the psychological state of patients after head injury, the relationship of head injury to subsequent epilepsy, the use of encephalography as a diagnostic measure, the prevention and treatment of headache and other complications, and the rehabilitation of brain-injured patients. Similarly a Nerve Injuries Committee, under Brigadier G. Riddoch, prepared memoranda on methods of testing for peripheral nerve lesions and the assessment of their recovery, and also sponsored investigations into the value of operative treatment for sciatica caused by prolapsed intervertebral disk.

Traumatic shock was the subject taken by another group, which surveyed the existing state of knowledge on that subject and directed the resumption of active research. A great volume of clinical, pathological, and experimental evidence regarding the different manifestations and treatments of shock due to wounds and burns was accumulated, but the compilers of the report say that there are many gaps in knowledge to

be filled, and the implication of many of the more important studies made by British, American, and other workers during the war requires correlation.

"Thus the precise roles of haemorrhage, of plasma loss, of tissue damage, of associated biochemical changes, and of nervous influences in producing the altered haemodynamics causing acute illness after injury, require to be established and integrated; and the relationship of renal failure in the 'crush injury syndrome' to other forms of 'traumatic' and 'non-traumatic' anuria, and perhaps to the toxæmia deriving from the infective muscle necrosis of gas gangrene, has still to be fully elucidated."

But the main pieces of the puzzle have been fitted together, and if in peacetime the interest in the reactions of the body to injury can be maintained, and the opportunities for research afforded by traffic and industrial accidents can be effectively used, substantial advances may come in the near future.

War Diseases

The Council supported or co-ordinated important programmes of research concerning malaria, the typhus fevers, infective hepatitis and serum jaundice, and tuberculosis. The two outstanding contributions to medical research on malaria during the war period have been the effective introduction of malaria suppression by mepracine and the synthesis by British workers of "paludrine." Mepacrine was strategically decisive in the overthrow of Japan, permitting military operations to be conducted successfully in hyperendemic malaria areas. The vast potential importance of D.D.T. as an insecticide and larvicide in malaria control must also be recognized.

In 1944 the Scrub Typhus Commission was set up, travelled to the headquarters of the Supreme Commander South-East Asia, and undertook an active campaign to reduce the incidence of the disease, which had reached alarming proportions. A vaccine against scrub typhus was found to give a fair degree of protection to mice, and, although there was still lack of positive scientific evidence of protection in man, the position in the South-East Asia Command was so urgent that mass production of the vaccine was undertaken and the material sent out east. The sudden end of the war against Japan, however, prevented the assessment by the Army of the efficiency of the vaccine. Further field trials among civilian population have been organized, and the results, when available, should be of great interest.

The investigation of infective hepatitis proved most arduous. In spite of some promising results the transmission of the virus to animals has not yet been achieved with certainty. It was necessary to use human volunteers, and patients with rheumatoid arthritis were mostly chosen because it was known that the symptoms of that condition were sometimes relieved by an attack of jaundice. That was indeed borne out by the experiment, but the remission was only temporary; and it was clear that while jaundice was a useful research "tool" for the study of rheumatoid arthritis it could not be recommended as an effective treatment, and research on these lines was abandoned. The two most important discoveries made in connexion with this disease were that the virus is present in the blood of post-arsenical jaundice, and that the virus is excreted in the faeces in infective hepatitis. Without a susceptible animal, however, it is impossible to bring the research to the final goal of a prophylactic vaccine.

The report recounts the work done in wartime tuberculosis by the introduction of routine mass radiography, also the investigations on what is now recognized as a third mammalian type of tubercle bacillus—the murine type (the vole acid-fast bacillus). Plans for a field control to determine the prophylactic value in man of B.C.G. and of the vole bacillus are being considered.

Louse infestations were studied on a large scale, but with the advent of D.D.T., which played a large part in checking the Naples typhus epidemic, the troops engaged in the fighting on the Continent after D-Day were kept virtually free of lice. It is recalled that D.D.T. was first synthesized in 1874, but not until 1940 had its insecticidal properties been appreciated; and even then it was used only in Switzerland on a limited scale against agricultural pests. Not until early in 1943 was its large-scale production begun as an insecticide against one of the minor horrors of war. Scabies was also the subject of thorough investigation. The parasite was shown to be usually transmitted

by intimate personal contact, and as a result the disinfection of bedding has been given up by many progressive public health authorities, who now concentrate attention on the persons infested and their immediate contacts. It has been shown that when properly applied one treatment with benzyl benzoate emulsion will cure the disease in very nearly 100% of cases, so that disinfection of clothing and bedding is unnecessary.

Development of Penicillin Therapy

Eighteen pages of this report are devoted to the history, and development of penicillin therapy. The investigations on penicillin at the Sir William Dunn School of Pathology, Oxford, were supported by the Council from the beginning of the work which led to the introduction of penicillin into medicine as a chemotherapeutic agent. The early laboratory experiments at Oxford are narrated—the protective experiments in animals, the establishment of the "Oxford unit" of penicillin activity, the early efforts to increase production, the clinical trials, the use of penicillin in war wounds and burns (conditions which in the early stages had first priority at a time when the amount of penicillin available sufficed only to supply each of four centres with about 6 million units of penicillin monthly), and the gradually extending availability until by 1944, when the invasion of Normandy was about to begin, there was ample penicillin for all who needed it. By that time the Army Medical Service was able to organize on the widest possible scale prophylactic treatment against sepsis by parenteral injections beginning within 24 hours of wounding. The high quality of war surgery and the provision of penicillin reacted upon each other. Much of the success attending the use of penicillin was due to the very efficient surgery and such surgery again received a stimulus because surgeons who were provided with penicillin were able to suture even the most severe wounds without the danger of major sepsis.

"Almost the whole of the work on which the present knowledge of penicillin therapy is based was done in Great Britain and the United States. Although penicillin was a British discovery, United States workers had the advantage of enormously greater supplies of the drug in its early years, and in many centres in America had begun before anyone outside Oxford had handled penicillin in England, and American output reached a spectacular level while ours was little more than a mere trickle. Only when American penicillin was placed at the free disposal of our fighting Services was it possible for British clinicians to use it on an adequate scale. Nevertheless, it was in the early days of scarcity that the most substantial contributions to knowledge were made by British investigators, and these, almost without exception, were working on behalf of the Council."

The setting up of the Penicillin Clinical Trials Committee, under the chairmanship of Prof. H. R. Dean, is described. This committee was set up in the early part of 1943, its function being to increase knowledge of penicillin therapy by developing improved technical methods of administration and by extending the range of use of the drug to include conditions in which experience of its action was lacking; of these latter conditions many were caused by bacteria known to be susceptible *in vitro* to the action of penicillin. The committee had to steel its heart against humanitarian considerations because for many months the scarcity of penicillin was such that treatment had to be refused to cases in which it would no doubt have been beneficial but would not have advanced knowledge of the action of the drug. There was not nearly enough penicillin even to treat the cases of staphylococcal septicaemia which came to the committee's notice, and of all diseases this is the one which most imperatively demands penicillin treatment.

The most recent activity of the committee has been to investigate the treatment of subacute bacterial endocarditis on a scale large enough to provide information as to the system of dosage best suited to the disease. A preliminary report on this investigation (*British Medical Journal*, 1946, 1, 381) showed clearly that while the scale of penicillin dosage appropriate to diseases other than subacute bacterial endocarditis is usually ineffective in that condition the administration of larger doses for 28 days or more can almost always cure it in its early stages.

The Wartime Drug Position

Some interesting history is contained in the section of the report which deals with the drug position in wartime. Those

who lived through the 1914-18 war will remember that a serious position arose owing to the shortage of certain drugs the supply of which up to then had been forthcoming from German chemical firms. In 1939 steps had been taken to ensure an accumulation of adequate stocks of natural and synthetic medicaments of foreign origin. The large-scale manufacture and supply of certain antitoxins and other immunological products for which there was likely to be a heavy demand under war conditions was also undertaken. British equivalents of the more important synthetic drugs and diagnostic agents hitherto obtainable only from enemy countries were manufactured here, and when considered advisable—that is, when the chemical identity of the British substitute with its foreign prototype was not entirely identical—were submitted to special clinical trials. Thus mepacrine was substituted for the German "atebrin," pamaquin for "pamaquine," bromethol for "avertin," soluble hexobarbital for "evipan sodium," iodoxyl for "uroselectan-B," phenylephrine for "bilsselectan," and pethidine for "dolantin" or "dialtol," a synthetic substitute for morphine.

A Therapeutic Requirements Committee was set up under the chairmanship of Prof. L. J. Witts, on which the three bodies producing official drug formularies were represented—namely, the Pharmacopoeia Commission, responsible for the *British Pharmacopoeia*; the Pharmaceutical Society, for the *British Pharmaceutical Codex*; and the Insurance Acts Committee of the British Medical Association, for the *National Formulary*. The functions of this committee were to advise the controllers of the import and manufacture of drugs which were vitally necessary and must be supplied at all costs. It informed the medical profession, more particularly the key people responsible for formularies, indents, and quotas, of such important drugs were scarce and must be used economically. Generally it dealt with the problems which inevitably arose when any form of restriction is practised. Instances are given of the changes in therapy which gave rise to supply problems of varying degrees of complexity, such as the replacement of sulphur by benzyl benzoate in the treatment of scabies, the replacement of tannic acid by sulphonamides and penicillin in the treatment of burns, the sequence of safrol, lethane, and DDT in the treatment of louse infestation, and the use of thiouracil, thiothiouracil, and methyl thiouracil in the treatment of hyperthyroidism.

The more permanent effects on prescribing produced by the war's activities during the war remain a subject for speculation. In general they were the acceleration of changes which would have come more gradually in peacetime, an acceleration which was in line with expert direction and the avoidance of vested interests and unsupported tradition. Single substances and active principles were used instead of tinctures and mixtures; the many hospital pharmacopoeias, which are chiefly of historical interest, were replaced by the *National War Formulary* of the Ministry of Health. The use of foreign or proprietary names was discouraged. Synthetic chemicals were substituted for galenic drugs. Bismuth only gave way to magnesium trisilicate and aluminium hydroxide in the treatment of dyspepsia, boric lint was replaced by the sulphonamides and penicillin. Production of needless varieties of hypnotics and local anaesthetics was temporarily checked. Finally, a demand was created for disinterested accounts of the increasingly rapid developments and changes in pharmacology, and their scientific application to the practice of medicine.

The Drug Requirements Committee recently appointed by the Ministry of Health has now taken over the functions, as applied to post-war conditions, of the Therapeutic Requirements Committee, which was discharged on the completion of its wartime task.

Nutritional Standards

At the outbreak of the manner in which rationing was introduced, the nutritional investigations which preceded it, and the work which led to a recasting of Service rations and for the armed troops, and for tropical climates. In 1943 a committee was appointed under the chairmanship of Dr. A. N. Richards to examine the nutritional state of the people in the United Kingdom during the war. The main index of the nutritional state was taken to be the haemoglobin content of the blood. In a survey of 11,000 adults and 3,000 children were examined. A smaller number of serum protein estimations were made. From these it was concluded that the nutritional state was generally good, though an effort was made to maintain the haemoglobin levels of young

children, pregnant women, and the poorer members of the population.

The work of the Accessory Food Factors Committee was concerned with the composition of wartime bread and the vitamin content of various foodstuffs, but the work of the Food Rationing (Special Diets) Committee, with Sir Edward Mellanby as its chairman, was the most exacting and difficult of all. This committee had the task of organizing food rationing for invalids. It received, as was to be expected, innumerable special applications for extra rations, often from sufferers from rare diseases or from variants of illnesses for which extra rations had already been refused. Each case was considered individually, specialist advice was sought where necessary, and a written statement was made of the reasons for or against granting extra rations. The body of rulings which accumulated from these decisions came to play an important part in the system of rationing. The committee must often have been gravely troubled when it came to deciding the order of priority in the claims of invalids for extra rations when the humanitarian impulse was to grant them all if only there was a sufficiency of food available. Certain principles were laid down: that extra rations should be granted only on the grounds of therapeutic necessity; that in deciding between competing claims preference should be given to those invalids with better chances of recovery or those who required special rations to maintain active health; and that extra rations should not be allowed for the construction of those traditional dietaries for invalids and convalescents which, however comforting to the patient, are without known effect on the ultimate outcome of his disease. The heartburning and the depression which must have resulted among invalids and their doctors as a result of these decisions can be imagined; but the nation was at war, and civilians, including invalids and convalescents, were in the front line in more senses than one. Except for an extra allowance of tea to the elderly, they, with hopeless invalids, the insane, and the mentally and physically defective, were denied any concessions unless they suffered from another condition which itself qualified for extra rations.

Special Diet Problems

As a result of seven years of rationing a unique experience was acquired of rationing as applied to invalids. Some of these results are set out. A generous allowance of fat was provided to meet the needs of diabetics because, by greatly restricting their intake of carbohydrate and substituting fat, they can avoid or restrict the use of insulin. Patients with pernicious anaemia were as a rule refused fresh liver, because experience has shown that treatment with fresh liver is far less efficient than the parenteral injection of liver extract. Fresh liver was allowed only where there was a supposed sensitivity to the extracts.

Patients with tuberculosis had been accustomed to receive a full diet, particularly one rich in fats. Certain studies undertaken just before rationing began to be severe showed, however, that fat had no advantage over carbohydrate; also that after two to three months on a high-fat diet the appetites of tuberculous patients declined and their weights fell, effects not observed on a high-carbohydrate diet. Carbohydrates being available in ample quantities, the committee held a watching brief, and after further inquiries and reports the only special rations allowed in tuberculosis were 2 pints of liquid milk daily in active—i.e., unhealed—tuberculosis, and later, when the cooking-fat ration was reduced, supplies to these patients were continued at the previous level.

An outbreak of alleged "food sensitivity" following the institution of rationing caused a good deal of trouble. As soon as it was announced that butter was to be rationed, innumerable margarine-sensitive people made application for extra butter, but the number of applications declined abruptly as soon as it was known that these people would be put through a test requiring them to distinguish margarine from butter when the taste was disguised. Similar complaints of sensitivity coincided with—in some cases actually anticipated—changes in the type of flour. Tests here gave little support for the view that persons can be sensitive to National flour but insensitive to white flour. Applications were made for condensed milk because of alleged sensitivity to raw cow's milk. In such cases the applicant's doctor was advised to order the milk to be boiled, and the measure appeared usually to suffice.

MAY 15, 1948

MEDICINE IN THE 1939-45 WAR

BRITISH
MEDICAL JOURNAL

The proposal to add calcium carbonate to National flour evoked a storm of protest. Diverse ill effects, ranging from the development of arterio-sclerosis to nephrolithiasis, were predicted. One eminent physician wrote alleging that he and his whole family were being poisoned by the added calcium whereas calcium salts were first added to the flour three months after the receipt of his letter! Actually the amount of calcium added to flour was hardly more than that needed to compensate for the amount of phytic acid it contained.

The Special Diets Committee is now anticipating the period of derationing, though it is already evident that any amelioration in the food supply position will develop slowly and piecemeal. But plans should be laid in advance so that, with increase of supplies, distribution can be made to the best advantage. All the conditions for which extra rations have been refused have been analysed and classified according to the order of priority in which the refusals should be rescinded. This is good news for chronic invalids and perhaps also for those people who have a sensitivity for certain foods, even though in the view of the experts such sensitivity is more imagined than real.

Various Emergency Services

A section of this report is allotted to what is called "Personnel Research," chiefly in connexion with the fighting services. This included studies of suitable clothing or armour for fighting men in widely different environments, and of the physiological and psychological adjustments which it is possible to make to hazards and unusual situations. Health research in industry was undertaken by the Industrial Health Research Board, and included studies in ventilation and air hygiene, heating, industrial psychology, and diseases due to inhaled dusts or poisonous fumes.

Among the emergency services set up was one for the co-ordination of the supplies of serological products and the provision of large stocks of polyvalent gas-gangrene antitoxin and reserve supplies of a number of vaccines and sera. The emergency public health laboratory service has been placed on a permanent basis to meet peace-time calls. In this service during the war special studies were made of non-pulmonary tuberculosis, cerebrospinal meningitis, and cross-infection in hospital wards.

The organization of the blood transfusion service called for careful planning. The four London emergency blood supply depots, situated at Luton, Maidstone, Sutton, and Slough, enrolled 128,320 donors during the five years of war. Research was also carried out on precise methods of blood grouping, and on the rare accidents which followed transfusion, and the measures to be taken to meet it. Another activity was the setting up of a possible risk of post-transfusion jaundice and the measures to be taken to meet it. Another activity was the setting up of a hospitals radon centre at Barton in Bedfordshire, where the radon plant, in view of the danger of the dispersal of radioactive substances by enemy action, was kept in safety in deep caves. Radium was lent to the centre by the Radium Commission and by St. Bartholomew's, and the three radon plants at Barton dealt with about 9,500 requests for radon for use in treatment or research.

Many Research Teams

The remainder of the report is a summary of the work done by each of several institutions—the National Institute for Medical Research, twenty or so external establishments, permanent or semi-permanent, the temporary units, and other research groups. At the central institute at Hampstead and the laboratories at Mill Hill work was done on problems connected with traumatic shock, underwater physiology, influenza (a continuing research throughout the war), air-borne infections, chemotherapy of virus diseases, anaerobic and other wound infections, immunization against tetanus, diphtheria, and gas gangrene, and on certain problems in biophysics and biological chemistry. Here also much work was done and made available. Three new standards were provided and made available at Hampstead during the war—those for the National Institute for Medical Research, an out-station of the National Institute was the Common Cold Research Unit at Salisbury. In the Departments of Clinical Research at University College and Guy's studies were made of the symptoms of shock in air-raid casualties. At the Neurological Research Unit at

Queen Square various factors connected with high altitude flying were investigated. At the Otolological Unit at the same hospital work was done on deafness and hearing-aids. The Birmingham Accident Hospital had a unit concerned with the epidemiology, prevention, and treatment of wound infection, and at the same hospital and at the Glasgow Royal Infirmary other units studied the control of infection in burns and scalds. In a research unit at Hammersmith Hospital an experimental comparison was made between gamma rays and x rays in the treatment of cancer of the mouth and throat; a full report of this experiment has been prepared for publication. Important dietary studies have been carried out in the Department of Experimental Medicine at Cambridge, at the Nutrition Building at Mill Hill, and at the Human Nutrition Research Unit at the National Hospital, Queen Square. At the Dunn Nutritional Laboratory, Cambridge, an analysis was made of fortified products such as vitaminized margarine and special food preparations. Several establishments were devoted to research on health in industry, notably the Department for Research in Industrial Medicine at London Hospital, the Applied Physiological Department at the Cambridge, and the Industrial Physiology Department at the London School of Hygiene and Tropical Medicine. At the London School also the effects of bombing on the civilian population and the protective value of shelters and other precautionary measures were studied.

The special work on diseases of children carried out by members of the Council's staff at the Queen Elizabeth Hospital for Children, London: on the pathology of the nervous system at the London Hospital, on biologically effective radiation at the Strangeways Research Laboratory, Cambridge, and many other investigations deserve permanent recognition. About 250 special investigations by outside workers, individuals or small teams, were supported by grants from the Council. The main burden of the editorship of this well-compiled report has fallen upon Dr F. H. K. Green, formerly Publications Officer, and now Assistant Secretary of the Council.

PUBLIC HEALTH CENTENARY

To commemorate the centenary of the Public Health Act, 1848, and in particular the appointment of Sir John Simon as the first medical officer of health for the City of London, the Lord Mayor and Corporation gave a dinner at Guildhall on May 7. The Minister of Health, Mr. Aneurin Bevan, was present with three of his predecessors, Lord Addison, the first Minister of Health, Lord Kennet (formerly Sir Hilton Young), and Mr. Ernest Brown. With the help of the archivists of the City a series of exhibits was arranged illustrating the Corporation's interest in public health, especially in water supply, cleansing of streets, and abatement of grosser nuisances, far back as the thirteenth century.

Mr. Aneurin Bevan proposed "The Pioneers of Public Health." The task which the reformers had faced in 1848, he said, was formidable. They were opposed by many vested interests. "Property and bumbledom fought together to deny the child the right to live." No one at that time thought of public health as a good investment. Even the great political figures of the day withheld their support from this cause. John Bright spoke only once on this subject, and that was to oppose a measure of smoke abatement. The pioneers whom Mr. Bevan asked the company to honour were Edwin Chadwick, John Simon, and William Farr. Chadwick fearlessly made public the conditions under which the industrial population was existing, and in doing so incurred much enmity. John Simon, who after seven years in the City became medical officer of the Privy Council, and finally first medical officer of the new Local Government Board, designed many administrative measures to alleviate social evils. William Farr, the statistician, might be described as the first to show the advantage of a Government scheme of national health insurance, and in his unceasing efforts for preventive medicine this son of a farm labourer had been a source of inspiration right down to our own time. To these names Mr. Bevan added the name of one politician, Lord Morpeth, afterwards Earl of Carlisle, who introduced the Public Health Bill in 1848.

Sir George Elliston, chairman of the Public Health Committee, proposed the health of the guests, to which the first of three responses was made by Lord Addison. Lord Addison recalled that with the assistance of the late Sir Robert Morant and Sir George Newman he was called upon to draft the provisions relating to maternity and child welfare which found their place in the budget of 1914. So much was the new service appreciated that early in 1917 a committee was set up consisting of Lord Milner, Mr. Arthur Henderson, Mrs. Beatrice Webb, and himself to consider the question of the establishment of a Ministry of Health. It took only two weeks to arrive at a unanimous report, but difficulties arose when it came to the actual establishment of the Ministry, and terms had to be made with local authorities and approved societies, so that not until 1918 was blessing formally given to the project. He became the first Minister in 1919, and was succeeded by Lord Melchett in 1921.

Responses were also made by the Bishop of London, who spoke of the function of the Church in the field of public health, and by Sir Alfred Webb-Johnson, who reminded the company that Sir John Simon was not only a pioneer in public health but a great surgeon, and indeed one of his predecessors in the presidency of the Royal College. Sir Alfred touched briefly upon present or subsiding controversies, as did Lord Balfour of Burleigh, chairman of the Medical Research Council, who wished goodspeed to the Minister and to the medical profession in their endeavours to bring in the new health service. Lord Balfour proposed the health of the Corporation, and the Lord Mayor (Sir F. Michael Wells) replied.

SEA AND AIR PORT HEALTH AUTHORITIES ANNUAL CONFERENCE

The forty-ninth annual conference of the Association of Sea and Air Port Health Authorities of the British Isles was held at Swansea on May 12, 13, and 14, under the presidency of Commander William Evans, chairman of the Swansea Port Health Committee. The delegates were welcomed by the Mayor Councillor Sir William A. Jenkins, J.P. At the annual general meeting held on the first morning of the conference Alderman L. E. Mooney, of Newport, was elected president for the year 1948-9. Dr. H. C. Maurice Williams, of Southampton, was re-elected honorary secretary, and Dr. W. M. Frazer, of Liverpool, honorary treasurer.

Golden Jubilee

To mark the Association's fiftieth jubilee, Dr. Nicolas Gebbie, port medical officer to the Hull and Goole Port Health Authority, gave an address entitled, "The Romance of the Port Health Service and of its Association." The idea of forming the Association, he said, was conceived by the Hull and Goole Port Sanitary Authority, which with other authorities realized that concerted action was needed to safeguard the health of seafarers. The first president was Dr. Fraser, a general practitioner and chairman of the Hull and Goole authority. Dr. Gebbie described the work carried out by port health authorities, and he reminded the conference that a further problem had developed during recent years—namely, the prevention of the introduction of infectious disease by air traffic. He described some of the early outbreaks of cholera in this country. The disease was unknown outside Asia until 1817; it then spread to the West in four great waves, reaching England via the four main lines of travel from India: through the Arabian Sea to the Arabian routes to Russia; by the Gulf of Persia to Suez and Egypt, and across the Caspian to Russia; by the Red Sea, thence to Egypt and the Mediterranean; and by the Trans-Caspian railway and the Black Sea to the Crimea. The infection came to England via the Mediterranean and Germany through the North Sea ports in 1817, 1818, 1819, and 1820. In the 1831-2 epidemic there were 21,000 deaths in England and 6,000 in Scotland. Further outbreaks occurred in 1846-7, in 1854, and in 1855-6. The Association was founded by a

Lambeth clergyman to insure his parishioners against cholera during the 1854 outbreak.

Port sanitary authorities were the first line of defence against cholera, and their defence was strengthened by the formation of their Association in 1898. The work of the Association had extended with that of its constituent authorities, and its advice had been sought on many occasions by national and other bodies.

Naval Hygiene

Surgeon-Captain Hugh M. Willoughby, deputy medical officer of health, Port of London, described his experiences as a hygiene officer in the Royal Navy at Alexandria. During his first two years in the Eastern Mediterranean there was no major epidemic of infectious disease. A few cases of dysentery occurred, but the incidence was kept low owing, in his opinion, to the ban on the eating of salads, melons, and fruit such as strawberries. Referring to "gyppy tummy," the speaker considered bacteriophage useful both as a prophylactic and in treatment provided that it was made from a local strain of the infective agent.

The incidence of malaria was low. There were only 29 cases reported during 1940, the majority infected in Crete and Greece. One of the greatest problems was supplying fresh water to Tobruk. All fresh water had to be conveyed in carriers previously used as oil and petrol tankers. Owing to good propaganda and recreational facilities, the incidence of venereal diseases in Alexandria was lower than in any home port in England.

Cholera in Egypt

Dr. R. Barrett, of the Ministry of Health, read a paper on the Egyptian cholera outbreak of 1947 and its effect on civil aviation. Egypt had suffered two epidemics of cholera in the past century. The first, in 1902, resulted in 34,000 deaths in a population of 5 millions. This epidemic was traced to the clandestine return of pilgrims from Mecca. Egypt had always been a centre of international sea and land traffic, and was now also an important centre of air traffic. Air routes radiated from Cairo to all parts of Europe, Asia, and the Far East, Australia, New Zealand, Africa, and North and South America.

For climatic and economic reasons Egypt was a country where at certain seasons cholera could develop in epidemic form. Its sudden reappearance in 1947 caused considerable anxiety. The epidemic appeared to have no connexion with the pilgrimages to Mecca. The first cases were notified as food-poisoning and occurred in a native village with a primitive sewerage system and a water supply that came from a shallow well. The main occupation of the inhabitants consisted of cultivation dates, pressing them into cakes, and selling them to other villages in Lower Egypt. In spite of immediate precaution the disease spread to the neighbouring villages and provinces until all the provinces in Upper and Lower Egypt, with one exception, were reporting cases of cholera. The last case was reported on Dec. 31, 1947, and six weeks later Egypt declared herself free from cholera. The total number of deaths in the outbreak was 10,383 in a population of 10 millions. It was significant that the disease did not get a hold in any of the cities where water supplies and sewerage systems were of modern design. The Egyptian Government took elaborate precautions to prevent the epidemic from spreading.

Dr. Barrett said that it was a matter for speculation whether the epidemic ended as a result of the seasonal drop in atmospheric humidity and the fall in temperature or because of the preventive measures introduced. The need for international agreement on measures for the sanitary control of aerial navigation was well demonstrated by this epidemic.

Aircraft having a case of cholera on board must undergo medical inspection, isolation of the sick, and surveillance of passengers and crew for five days (the internationally agreed incubation period), disinfection of passenger effects and parts of the aircraft, and disinfection of the drinking water. Medical inspection of all passengers and crew and surveillance for five days was also prescribed for any aircraft from an infected area. Only in one instance was a suspected case of cholera reported in an aircraft, at Darwin, and that was not confirmed bacteriologically. The only measures, therefore, that should have been imposed on any other aircraft or passengers were medical

MEDICAL JOURNAL

941

inspection and surveillance. In fact, during the time of the epidemics seven countries closed their frontiers to air traffic from Egypt. Another stopped air traffic to deal with any cases of cholera. Others restricted air traffic to one airfield.

Inoculations against cholera did not provide absolute protection, and therefore inoculated passengers were still subject to surveillance under the Conventions. The procedure adopted for inoculation varied, some countries insisting on two inoculations, others requiring certificates to state the number of vibrios injected. Two countries insisted upon negative stool examinations before entering. The effects, therefore, on air services were severe, and many of the countries introduced measures outside the scope of the requirements of the International Conventions. Such difficulties did not normally arise with maritime traffic, and this was a problem for which both Governments and airlines would have to find a solution. He suggested that there should be a standard procedure and that the vaccine should be standardized, as in the case of yellow fever.

During the conference the delegates visited several places of interest, including docks at Swansea and Port Talbot, the National Oil Refinery, Skewen, the Metal Box Factory at Neath, and the Imperial Chemical Industries Works at Warrarwydd.

NATIONAL HEALTH SERVICE DESIGNATION OF LONDON TEACHING HOSPITALS

Mr. Aneurin Bevan, the Minister of Health, has made the National Health Service (Designation of Teaching Hospitals, No. 2)* Order, 1948, under the provisions of the National Health Service Act, 1946, designating 26 teaching hospitals in the London area. The 26 designated hospitals comprise a total of approximately 60 constituent hospitals. The names of all the hospitals concerned are given in the Order.

Each designated teaching hospital will be administered by a new Board of Governors, who will shortly be appointed by the Minister when he has considered the nominations and recommendations of various authorities and organizations who are concerned.

The teaching hospitals so designated under the Act have been given a separate identity and status, and in addition to their primary function of treating the sick they will provide facilities for clinical teaching and research in accordance with the needs of the undergraduate medical and dental schools and post-graduate institutes of the University of London.

As the group comprising each teaching hospital will be one entity for formal administration it has been necessary in some cases to give it a new title. But the Minister would wish the names of the constituent hospitals, many of which are of long standing and have valuable associations and traditions, still to be used for everyday purposes.

The first Order, made early in April, designated Teaching Hospitals in the Provinces.

Hospital or Group of Hospitals (2)	
Title (1)	
The Royal Hospital of St. Bartholomew	The Royal Hospital of St. Bartholomew, E.C.1 (including the Alexandra Hospital for Children with Hip Disease, and the Zachary Merton Convalescent Home, Northwood).
The London Hospital	The London Hospital, E.1 (including the Croft Home, Reigate, the Marie Celeste Annexe, Reigate, the Zachary Merton Annexe, Banstead, the London Hospital Annexe, Brentwood, and the Herman de Stern Convalescent Home, Felixstowe).
	Queen Mary's Maternity Home, Hampstead, N.W.3.

Hospital or Group of Hospitals (2)	
The Royal Free Hospital	The Royal Free Hospital W.C.1 (excluding the Eastman Dental Clinic).
	The London Fever Hospital, N.1.
	The Elizabeth Garrett Anderson Hospital, N.W.1 (including the Rosa Morrisson House, New Barnet, and the Garrett Anderson Hospital Maternity Home, Belsize Grove).
	The Hampstead General Hospital and North-West London General Hospital, N.W.3.
	The Children's Hospital, Hampstead, N.W.3.
	The North-Western Hospital (L.C.C.), Hampstead, N.W.3.
University College Hospital	The North London or University College Hospital, W.C.1 (including the Obstetric Hospital and the Royal Ear Hospital, Huntley Street, W.C.1).
	The Hospital for Tropical Diseases, W.1.
	St. Pancras Hospital (L.C.C.), N.W.1.
The Middlesex Hospital	The Middlesex Hospital and Cancer Wing, W.1 (including the Middlesex Branch Hospital and Hulke Endowed Convalescent Home, Clacton-on-Sea).
	The Woodside Hospital for Functional Nervous Disorders, N.10 (including the Country Branch, Welders House, Chalfont St. Peter, Bucks).
	The Hospital for Women, Soho Square, W.1.
	The British Red Cross Society's Clinic for Rheumatism, Peto Place, N.W.1.
Charing Cross Hospital	Charing Cross Hospital, W.C.2.
	Harrow Hospital, Roxeth Park, Harrow-on-the-Hill.
	Wembley Hospital, Fairview Avenue, Wembley.
St. George's Hospital	St. George's Hospital, Hyde Park Corner (including the Adamson Morley Convalescent Hospital, Wimbledon).
	The Victoria Hospital for Children, S.W.3 (including the Victoria Convalescent Home, Broadstairs).
	The Princess Beatrice Hospital, S.W.5.
	The Royal Dental Hospital of London, W.C.2.
Westminster Hospital	Westminster Hospital, S.W.1 (including the Westminster Hospital Convalescent Home, Chatham Park, Sussex, the Westminster Hospital (Parkwood) Convalescent Home, Swanley, Kent, and the Yarrow Home of Westminster Hospital, for Convalescent Children, Broadstairs, Kent).
	The Infants Hospital, S.W.1.
	The Gordon Hospital for Diseases of the Rectum and Colon, S.W.1.
	All Saints Hospital, S.E.11.
St. Mary's Hospital	St. Mary's Hospital, W.2 (including Joyce Grove House, Nettlebed, Oxon., and Adair Lodge, Aldeburgh).
	Paddington Green Children's Hospital, W.2 (including the "Clear Springs" Convalescent Home and the "Pinecroft" Convalescent Home, Lightwater, Surrey).
	The Princess Louise Kensington Hospital for Children, W.10 (including the Convalescent Home, 19-20, South Terrace, Lintonhampton).
	The Samaritan Free Hospital for Women, N.W.1.
	The Western Ophthalmic Hospital, N.W.1.
	St. Luke's Hospital for Advanced Cases, W.2.
Guy's Hospital	Guy's Hospital, S.E.1 (including the York Clinic, Nuffield House, and "Holmesdale," Nuffield, Surrey).
	The Evelina Hospital for Sick Children, S.E.1 (including the Eleanor Wemyss Recovery and Convalescent Home, Crazies Hill, near Reading).

*Statutory Instruments, 1948, No. 979: National Health Service (Designation of Teaching Hospitals (No. 2) Order). H.M.S.O., price 1d., post free 2d.

Table (1)

Hospital or Group of Hospitals (2)

King's College Hospital	King's College Hospital, S.E.5 (including the Baldwin Brown Convalescent Home, Camberley).
	The Royal Eye Hospital or Royal South London Ophthalmic Hospital, S.E.1 (including the Royal Eye Hospital Branch, Surbiton).
	The Belgrave Hospital for Children (including the Belgrave Hospital Convalescent Home, Minstead, Hants).
St. Thomas's Hospital	St. Thomas's Hospital, S.E.1.
	The Royal Waterloo Hospital for Children and Women, S.E.1.
	The General Lying-in Hospital, S.E.1.
	The Grosvenor Hospital for Women, S.W.1.
	The Roffey Park Rehabilitation Centre, Horsham, Sussex.
The Hammersmith, West London, and St. Mark's Hospitals	Hammersmith Hospital, W.12.
	West London Hospital, W.6.
	St. Mark's Hospital for Cancer, Fistula, and Other Diseases of the Rectum, E.C.1.
The Hospital for Sick Children	The Hospital for Sick Children, W.C.1 (including the Tadworth Court Branch Hospital, Tadworth, Surrey, "Runabouts" Convalescent Home, Chipping Norton, Oxon., and the Sarah Louise Convalescent Home, Hove, Sussex).
The National Hospitals for Nervous Diseases	The National Hospital, Queen Square, W.C.1 (including the National Hospital Convalescent Home, Finchley).
	The Maida Vale Hospital for Nervous Diseases, W.9.
The Royal National Throat, Nose and Ear Hospital	The Royal National Throat, Nose and Ear Hospital (including the Central London Hospital Division, W.C.1, the Golden Square Hospital Division, W.1, and the Dame Gertrude Young Memorial Convalescent Home, Castle Bar Hill, W.5).
The Moorfields Westminster and Central Eye Hospital	The Moorfields Westminster and Central Eye Hospital.
The Bethlem and Maudsley Hospital	The Bethlem Royal Hospital for Nervous and Mental Disorders, Beckenham.
	The Maudsley Hospital, S.E.5.
St. John's Hospital for Diseases of the Skin	St. John's Hospital for Diseases of the Skin, W.C.2.
The Hospitals for Diseases of the Chest	The Hospital for Consumption and Diseases of the Chest, S.W.3 (including the Brompton Hospital Sanatorium, Frimley, Hants).
	The London Chest Hospital, E.2 (including the London Chest Hospital Annexe, Arlsey, Beds).
The Royal National Orthopaedic Hospital	The Royal National Orthopaedic Hospital, W.1 (including the Country Branch and Convalescent Branch, Stanmore).
The National Heart Hospital	The National Hospital for Diseases of the Heart, W.1 (including the Country Branch, Maid's Moreton, Bucks).
St. Peter's and St. Paul's Hospitals	St. Peter's Hospital for Stone and Other Urinary Diseases, W.C.2.
	St. Paul's Hospital for Urological and Skin Diseases, W.C.2.
St. James's Cancer Hospital	The Royal Cancer Hospital (Free), S.W.3.
Queen Charlotte's Maternity Hospital	Queen Charlotte's Maternity Hospital, W.7.
The Chelsea Hospital for Women	The Chelsea Hospital for Women, S.W.3 (including the Chelsea Hospital Convalescent Home, St. Leonard-on-Sea).
The Eastern Dental Clinic	The Eastern Dental Clinic, W.C.1.

Reports of Societies

GENERALIZED DISEASES OF BONE

At a meeting of the Section of Medicine of the Royal Society of Medicine on April 27, Dr. MAURICE DAVIDSON presiding, the subject presented was generalized disease of bone in adults. There was no general discussion.

Dr. E. F. SCOWEN spoke of the effect of endocrine disorders on bone diseases. Wherever bone was formed the final part of the story must be the formation of a matrix which later became calcified. In the first place there might be a normal or an excessive quantity of matrix formed which might be irregularly calcified or not calcified at all—a condition arising from a disturbance of calcium or phosphorus metabolism. Another condition might arise from excessive resorption of bone even though bone formation was proceeding normally. Lastly, there might be failure of formation of the osseous matrix. This might not be complete, and, if partial, such bone as was formed might be formed normally and calcify normally, so that a condition of osteoporosis occurred. Dr. Scowen proceeded to show a number of photographs and radiographs illustrating endocrine abnormalities as reflected in bone changes. Certain changes seen in acromegaly had received little attention. In the thoracic spine irregular new bone formation might be seen, with decalcification behind it, giving rise to a curious appearance when the spine was viewed as a whole, the thoracic vertebrae appearing very much larger than the upper lumbar vertebrae. In the adult as a result of the stimulation of excessive bone production the vertebrae were still capable of producing a good deal of new bone, but such formation was often localized to the middle and lower thoracic vertebrae.

Method of Classification

Dr. J. F. BRAILSFORD said that the conditions which led to generalized diseases of bone might be grouped under five headings: (1) dysplasias and dystrophies which began in foetal or infantile life, and were of varying severity, some being incompatible with the continuance of life, while others were so slight that the victim survived into old age and the condition was discovered only incidentally on some radiographic examination; (2) generalized conditions of bone due to disturbance in some other organ—for example, renal disease; (3) generalized diseases of bone due to deficiencies and endocrine and blood disorders, for example, osteomalacia, hyperparathyroidism, anaemia, or leukaemia; (4) conditions which attracted attention during the major part of the illness only by the occurrence of a local lesion; and (5) a group of conditions in which the patient, who had been perfectly well, began to have pain and aching in the limbs, but for a year or even two years without perceptible radiographic changes—a group including syphilis and carcinomatosis. Dr. Brailsford suggested that the radiography of the hand facilitated the separation of these generalized conditions from conditions which, for the most part localized, gradually spread to other bones. Radiologically two types of reaction were seen, namely, the reaction which brought about a diminished density of the bone and the reaction which produced an increased density. In some conditions both reactions occurred, one after the other. By using the classification he had given he thought that these generalize diseases of the skeleton could be put into something like order.

It had been stated that hyperparathyroidism was a condition which in the majority of cases revealed itself by renal complications. That had not been his experience. The most striking feature was decalcification of the terminal phalanges, absence of compact tissue, and the formation of cysts in one or two of the bones. The formation of cysts in that type of osteoporosis was not seen in the same way in any other condition. On one condition approached it, namely, severe renal osteodystrophy, in which there was a history projected from childhood into the later years of life, with bones which had been deformed very early in life. In hyperparathyroidism the architecture of normal bone was presented, apart from lack of compact tissue whereas in renal osteodystrophy there was likely to be deformity.

REPORTS OF SOCIETIES

Correspondence

The characteristic feature of Paget's disease, which began as a localized lesion, was the tearing away in a V-shaped fashion of the periosteum from the adjacent living bone. Paget's disease might involve every bone in the skeleton, but normally this was not so. It might be that the head, spine, pelvis, and femur were extensively involved, yet on examining the bones of the hand only one metacarpal might be found affected, the rest of the bones being normal.

Sir HAROLD FAIRBANK referred to some unusual cases. Osteogenesis imperfecta might, for example, be of interest in a adult patient. One severe case, pre-natal in origin, was in a girl who never walked at all until 12 years of age, and sustained many fractures later on; she was now a dwarf aged 31, but was able to get about and carry on office work. A woman of 72 with "marble bone" was admitted to hospital with a minor head injury, and only then was the extreme density of the bones discovered. She had carried on for many years with practically no bone marrow at all. As an example of endocrine disorders he described the case of an intelligent well-proportioned dwarf of 46, most of whose epiphyses were still ununited, and the radiographs of whose skull showed what was apparently a partially calcified cyst of the pituitary.

ABDOMINAL PAIN

At a meeting of the Manchester Medical Society on April 7 Prof. JOHN MORLEY delivered his presidential address—"Second Thoughts on Abdominal Pain."

He recalled that the thesis he had advanced in 1931 followed James Ross's teaching of the dual nature of abdominal pain; but while accepting Ross's visceral pain he had suggested that the referred pain and the associated muscular rigidity, so far as the peritoneal cavity was concerned, were due to irritation of the parietal peritoneum. This conclusion was based largely on the clinical phenomena observed in cases of acute appendicitis. Recent injection experiments had confirmed the accuracy of these views. The initial visceral pain in acute appendicitis was transmitted through the splanchnic nerves but the second or localized pain was peritoneal. Pain in the shoulder-tip area felt or stimulating the phrenic nerve terminals in the diaphragm was a striking special instance of the radiation of pain from the parietal peritoneum, and, like the superficial pain in the right iliac fossa in appendicitis, could be modified by subcutaneous injections inducing analgesia of the area of referred pain.

The work of Lewis and Kellgren on referred pain was reviewed. Although Lewis claimed that there was no essential difference between deep somatic and visceral pain, his own experiments failed to produce any reflex contraction of the rectus abdominis muscle on stimulating the gastro-intestinal tract. The method used by Bentley and Smithwick to produce visceral pain by inflating a balloon in the jejunum before and after splanchnic neurectomy for hypertension was described. The afferent nerve fibres from their way to the cord, but through the splanchnic nerves on their way to the cord, had they could not properly be described as sympathetic had been suggested by Bentley and by Bonney and Pickering had been suggested that the inflammatory change associated with a peptic ulcer endowed the affected area of the stomach with a tenderness on direct mechanical pressure that was never found in the stomach or duodenum which was not inflamed.

The long controversy on the exact mechanism of the pain in peptic ulcer had ended in exposed nerve endings in the effect of hydrochloric acid acting on accompanying areas of the ulcer as the true explanation. Recent work on the ones of skin described by Wernöe as accompanying areas of referred pain had cast grave doubts on the general problem of pain. The bearing of cardiac pain on the occurrence of these visceral pain was discussed; Chester M. Jones and Henry Cohen had suggested a theory of summation of stimuli from both visceral and somatic sources as the most probable explanation of the phenomena of referred pain. Although they had failed to ignore the temporal factor in the summation of impulses, some such hypothesis would probably displace the time-honoured theory of an "irritable focus" in the cor-

Strength of the Profession

SIR,—The cumulative effect of the various plebiscites suggests some parallels and comparisons with the N.H.I. struggle which seem to me worthy of consideration. In 1912 we held no plebiscites of the whole profession, for only the general practitioners were directly involved, but we took a great deal of trouble to ascertain what they were prepared to do and the end result was not flattering to our efforts. If we had had then the clear indications which the recent plebiscite gives we might have been spared the humiliation which followed the declaration in December, 1912, that the R.B. considered the Act unacceptable, derogatory, and unworkable. On that day as Medical Secretary I had in my possession a flood of letters and telegrams from Divisional secretaries all over the country which told me that the local doctors were flocking to the panel because they had come to the conclusion that the concessions gained by the Association made it well worth their while to do so. The Association, influenced by some eloquent "diehards," refused to hear this evidence. Within a week requests for a Special Meeting came in from many Divisions. The meeting was held and the resolution rescinded—too late to prevent the Association from appearing foolish and inconsistent. Is history to repeat itself? It should not do so because the latest plebiscite shows that already a very considerable number of doctors have come to the conclusion either that it will be worth their while to join or that they cannot afford not to do so.

An interesting parallel is that in 1912 the Press and our chief opponents, the Approved Societies, told us we had won a great victory, but we preferred to concentrate on the comparatively minor points we had failed to achieve. The *Westminster Gazette* said: "We all admire the man who does not know when he is beaten. The trouble with the B.M.A. is that it does not know when it has won." In the *Economist* of April 24, 1948, I read the following words which reflect a considerable body of Press and public opinion. Undoubtedly the doctors have won a big victory, because we have easily climbed down to the extent that he has done.

I do not think we have won a big victory, because we have failed to hold what to my mind would be the chief security against a whole-time salaried service—namely, the right of private property in the goodwill of medical practices. But if the have wrung out the concession that this will not be introduced by Regulation or without a new Act of Parliament. But if the Labour Party should be returned to power at the next election they will be greatly tempted to carry out their declared policy, and in my opinion the best way of preventing this is to use the interval for providing such a satisfactory service that the public would be against any attempt to unsettle the profession once more.

In my opinion—and I say it with regret—to continue to oppose the working of the Service because we have failed on the goodwill issue would be to fly in the face of what is possible. I have three reasons for saying this: (1) we should not have behind us the number of general practitioners we have declared to be necessary for the continuation of opposition; (2) we have no friends for this principle in any of the political parties, and precious few if any in the Press; (3) and, to my mind conclusive, there is a very considerable number of general practitioners who (to my amazement) do not think it is a thing worth fighting for.

As an old medical politician, loving a good fight, I have never seen any good in refusing to face facts and in continuing to try to get the unattainable. I believe our best policy is to accept the verdict of the plebiscite ungrudgingly and to assure those doctors who join the Service that they will have the whole-hearted support of the Association in making the Service a credit to the profession. If we accept this policy much remains to be done, and time is short. The Regulations under which doctors will work must be examined, bringing to bear the unique Regulation-making experience gained in over 30 years of the N.H.I. And this experience will be equally valuable to the consultants and specialists who have no similar experience but

will all have to work under Regulations. And of course those doctors who choose to stay outside the Service must be assured of the help of the Association. Vigilance will be needed to ensure that neither they nor their patients will be penalized for their independence.

There never was a time when a strong Association was more necessary, not only for the protection of the doctor but for that of his patients. The great power and prestige earned by our Association during the past few years must not be frittered away, and I think that having proved that we can put up a good fight, and not abandoning our arms, we can do our best work now in the constructional field.—I am, etc.,

L. F. S. W. J.

ALFRED CON.

Balanced Statement

SIR.—To anybody who has followed the editorials of the *B.M.J.* during the past two months those of the last three issues must be a subject of derision. It is now an open secret that the Council was deeply divided on the question of the Minister's concessions: the minority was a considerable one. If we accept the best possible interpretation of their case we are nevertheless convinced that they must have known that the result of their decision must be disastrous—i.e., that the minority action would bring defeat to the majority. The attitude taken by the majority also deserves condemnation. It is true that Dr. Dain at Shrewsbury spoke in the old familiar style, but his letter (April 24, p. 805) was a confirmation of that "careful and balanced statement issued by the Council." This "balanced" statement, as the majority of the Council knew perfectly well, was bound to confuse the doctors' minds. If, then, this argument is well grounded, both the majority and minority deliberately committed themselves to a course of action which of necessity would deeply divide the profession as they themselves were divided.

What is not so clear is the manner in which the minority has captured editorial policy in the last three issues of the *B.M.J.* No impartial reader could say that these were "well balanced." The words may be this or that, but the horrid smell of appeasement comes up from all of those three articles. The *B.M.J.* is dividing the doctors, and it is doing so deliberately. On the eve of battle no general could maintain the morale of his troops by making a well-balanced statement which reflected the indecision and revolt of a minority of his high-ranking officers. The *B.M.J.* and the B.M.A. up to and including April 10 stimulated and sustained our effort admirably. We had the Independence Fund, all the material, all the organization, groups were formed under their conveners; meetings and rallies were held. Then the leadership faltered and failed. The half-hearted "balanced statement" took its place—for what good reason? Dr. Dain said at Shrewsbury on April 18: "Those who have studied the matter most do not consider that the doctors would be properly safeguarded by the Minister's proposals." Lord Horder, writing to the *Daily Telegraph* on April 22, said: "The situation so far as concerns the freedom of the doctors . . . remains unchanged. The Minister remains all-powerful." These men were in a majority. Why then the abdication of leadership?

Was the *Manchester Guardian* almost right on April 16 when it said: "The B.M.A. has to consider its position not only in the current negotiations but as the continuing spokesmen of a large part of the profession. . . . If a good number of doctors are brought by Mr. Bevan's belated concessions to change their mind, and enter the Service in any case (as seems probable) will the B.M.A. and the rest stay outside, its present strength will be reduced if it leads its following solidly into the scheme of entry, its strength and its negotiating power." The way is being laid for a coming announcement in the *Lancet*: "The profession has decided to accept," or "The profession is insufficient to warrant a continuation of the struggle," or "It is clear that may be superficially true the hard fact is that by means ever so subtle, 'balanced' statements which mislead the reader and a clever course of action the doctors were conditioned to accept the Service." Will you be good enough, Sir, to let the doctors know that you have printed so much about freedom of choice, and that of these things, you have achieved little

worth while. The doctors will be just as much the servant of the State machine as if the B.M.A.'s campaign had never started.—I am, etc.,

Burnley, Lancs.

H. SIMPSON,
Public Relations Officer,
Independence Committee.

Special Procedure for Regulations

SIR.—I believe that the vast majority of the profession learned with deep satisfaction that the Chairman of Council, in his speech to the Representative Body on March 17, had declared that "the overall considerations which determined 90% of doctors to record their disapproval of the Act had been that the Minister's power under the Act was absolute," and that "that power would lead to the enslavement of the medical profession which will come to be controlled in effect by the officers of the Ministry." Precisely the same feeling prompted the resolution passed by the Royal College of Physicians of London on March 22 which asked for a "special procedure," by way of a committee, that would serve as a check on Regulations. How urgent such check is becomes apparent from Sect. 66 of the Act, which empowers the Minister and his successors to determine by Regulations alone "the qualifications, remuneration, and conditions of service" of doctors and dentists and other employees under the Act.

When the Minister on April 7 made his statement in the House offering, in response to a request by the Royal College of Physicians, "to make it clearly impossible to institute a full-time salaried service by Regulation alone," I asked him if he would also take into consideration the second resolution passed by the College, asking for a "special procedure" committee. The Minister promised to do so. In his subsequent written answer to the B.M.A., which had endorsed the College resolution, the Minister declared that there is such a committee in operation, but he did not name it.

I am informed by the Table Office, and independently by the Lord Chancellor, that the Committee indicated is the "Statutory Instruments Committee," established by Parliament in 1944. The present chairman of that committee, in a letter (dated May 6) which lies before me, declares that its function "is to inquire only into the technical correctness of Regulations, and not into their merits." It is thus obvious that it would be wholly unfitted to perform the duties desired by the resolution cited. I submit that the demand for effective fulfilment of the request made by the resolution should be fully met in the Amending Act.—I am, etc.,

House of Commons.

E. GRAHAM-LITTLE.

Representation of Consultants and Specialists

SIR.—It is clear that there is widespread anxiety among consultants and specialists as to the most suitable body which should represent their views and interests. There is at present a choice between the Royal Colleges, the B.M.A. Consultants and Specialists Committee, the Association of Major (Non-undergraduate Teaching) Voluntary Hospitals, the London Consultants Committee, etc., and now we have proposals, on the one hand, from the British Medical Association for new central and regional consultants and specialists committees elected along democratic lines, and, on the other hand, from the leader writer of the *Lancet*, a new body based largely upon the Royal Colleges and teaching hospitals, with no evidence of a democratic constitution.

Under these circumstances, and particularly in view of the present emergency, the undersigned members of this hospital strongly support the immediate formation by the British Medical Association of new central and regional consultants and specialists committees, provided that they consist solely of consultants and specialists, with an independent secretariat, that their decisions should not be subject to being overruled by the Representative Body, and that these should be taken as being the policy of the Association in matters relating solely to consultants and specialists.—We are, etc.,

C. HEYGATE VERNON,

terms of tonic value

The value of a tonic cannot be measured in simple numerical units. But desiderata for such a preparation can be placed under well-defined functional headings . . . restoration, formation and protection. Syrup Minadex is well equipped to fulfill these functions. Iron, calcium and other minerals comprise the stimulatory and formative elements of Minadex. The vitamins A & D of Minadex are specific in a protective sense. Combined in an orange-flavoured syrup enjoyable to even the most fastidious patient, these factors restore lost appetite and hasten the return to full health.

in 4 oz. and 12 oz. bottles

Each fluid ounce contains: Vitamin A 15,000 i.u., Vitamin D 3,000 i.u., Iron and iron compound 13y grains, Calcium glycerophosphate 2 grains, other Minerals

GLAXO LABORATORIES LTD., GREENFORD, MIDDY.

Bonum magis carendo quam fruendo sentitur (Pr.)

RICE bran, which formerly was cast aside, is now recognized as one of the richest known sources of the B-complex. 'Beplex', an aqueous extract of rice bran, contains all the known factors of the B-complex, with extra amounts of thiamin and riboflavin. It is thus possible with a small dosage to administer large amounts of the B-complex in their optimum proportions. 'Beplex' is indicated for all sub-clinical 'B' deficiencies. It is available as an elixir or in capsules.

A good thing is appreciated more when it is lost than when it is being enjoyed.

BEPLEX

Elixir and Capsules
Each c.c. of Elixir contains: Thiamin Hydrochloride 10 mg., Riboflavin 100 mg., Nicotinamide 100 mg., Pyridoxine Hydrochloride 10 mg., Ascorbic Acid 100 mg. and other B-complex factors.

GANGRENE OF TOES

Repair of Skin with Cross-flap Replacement

A boy, aged 17, was admitted to Hospital on 22/10/45, having sustained a crush injury of 3rd, 4th and 5th toes, on the same day. Examination showed complete sensory loss on three toes with discoloration and obvious grave interference with circulation. Line of demarcation gradually developed and on 12/11/45 there was established gangrene as shown. (Fig. 1).

CASE HISTORY. — 16/11/45 Excision of gangrenous area and raising of delayed skin flap on R. calf. Pressure dressing, and penicillin cream to L. foot daily. 4/12/45 Flap on R. calf raised and attached to raw area on L. foot. Fixation in Gypsona with flap relaxed. (Figs. 2 and 3). 15/12/45 Sutures removed from flap graft. Showing satisfactory healing. 24/12/45 Under local anæsthetic flap detached from calf to foot; sutured in position. Remainder of flap sutured back to calf. 22/1/46 Complete take of graft. Penicillin applied. Commenced foot exercises. 29/1/46 Wound soundly healed. Dressing discontinued. Patient commenced walking. 11/2/46 Excellent result flap graft. No pain. Walking well in normal shoes. R. foot normal. No fibrosis of gastrocnemius. Discharged. (Fig. 4). *In the belief that it will be of general interest, details of this authentic case are published by T. J. Smith & Nephew Ltd., of Hull, Manufacturers of Elastoplast and Gypsona.*

INTRODUCING A SAFE AND EFFECTIVE SEDATIVE AND HYPNOTIC FOR REPEATED ADMINISTRATION

from the Laboratory of

T. & H. SMITH LTD.

TABELLÆ SEDATIVÆ

R Tab-Sedativ. (Smith)

These Tablets present a new combination, providing the well-tried sedative and hypnotic property of Phenobarbitone enhanced by the analgesic and antispasmodic action of Codeine.

INDICATIONS: Insomnia, neuralgia, cardiac neurosis, angina, bronchial and cardiac asthma, painful cough, whooping cough, causalgia, dysmenorrhoea, epilepsy, hysteria, migraine, mental disease, chorea, pruritus, and in many other conditions where a reliable combined hypnotic and analgesic is required.

EACH TABLET CONTAINS PHENOBARBITONE & GRAIN AND CODEINE PHOSPHATE & GRAIN, WHICH GUARANTEES ACCURATE DOSAGE AND CONVENIENCE OF ADMINISTRATION

MAY BE DISPENSED ONLY ON PHYSICIAN'S PRESCRIPTION

Physician's Sample free on receipt of signed order.

AND AT LONDON & GLASGOW

*so to bed... } ★
and so to rise }*

REFRESHED · RESTORED · REVITALISED

'Tabloid' Cyclobarbitone is the ideal barbiturate for routine sedation. It induces sleep within one-half to one hour, after which its hypnotic action rapidly diminishes and is replaced by a state of *natural* sleep. The patient awakes refreshed and free from the "hang-over" effects commonly produced by soporific drugs.

Right to Own Practice

SIR.—I am horrified and most disappointed by the tone of your leader in the *Journal* of April 17 (p. 737). The Minister of Health has consistently vilified and abused the medical profession since he first introduced his Bill. There are very many doctors who are in no way committed to, or in favour of, a comprehensive medical service, which is entirely a political movement with a Communist or State capitalism basis. If it was ever suggested by the B.M.A., it is so much the worse. I do not recollect that such a matter ever came to my notice as a member of the B.M.A. for over twenty years. The sole guarantee of freedom for any doctor is the right to own his own practice and to buy and sell as required. This right is recognized in any community which is not based on ideas of State capitalism, and if we give in on this point we cease to be independent individuals but automatically become State servants working on Government premises for a Government salary. Capitation rates are only a salary in a disguised form. It has been often said that the politicians would be more than a match for the doctors, and if the B.M.A. accepts the Minister's proposals, at their face value our Negotiating Committee has let us down.

Why all this anxiety to obtain a good press? The general public in this area are almost entirely against this State service, which is entirely politically inspired for the purpose of controlling doctors and public alike. I sent my contribution of £100 as advised as a means to winning our fight for freedom, not on the expectation that the B.M.A. would let down the doctors, and if we give in to the Minister now on account of his transparent and miserable concessions I shall be sadly disillusioned. There is no Government with any support from any part of the population except the Communists who could advocate the confiscation of my practice for a paltry 2½% per annum on its computed value, and any man or any association who permits this to happen is guilty of a completely immoral and illegal act. Before any plebiscite is taken full time must be allowed to discuss this latest attempt to put the State above the individual, and to degrade our country still further by nationalization for nationalization's sake. Once the medical profession goes down, the rest of the country will follow and we shall have lost a glorious opportunity of proving to the world that this country is not in favour of State capitalism. If we accept this Act, we are betraying the entire country.—I am, etc.,

R. MCINTOSH RATTRAY.

J. MCINTOSH RATTRAY.

Towards a Whole-time Salaried Service

SIR.—For a long time, especially during the last few years, we have been concerned in endeavouring to maintain the freedom of medicine and of its practitioners. To that end we have enunciated certain principles which have been approved and, up to now, adhered to by a practically unanimous profession. I do not intend to try to assess the relative importance of these principles or conditions; I will deal with one which, although mainly concerning general practitioners, cannot but be of importance to the whole profession. This is the question of the right of doctors to retain the ownership of their practices. For brevity, and I hope for clarity, I will speak only on its effect on the maintenance of freedom and independence.

Many of us are greatly concerned that this principle appears to have dropped somewhat into the background and that a number, perhaps a large number, of doctors consider that the Minister has met our requirements. If the profession agrees to surrender this principle, it is difficult, if not impossible, to see how our freedom or independence can be maintained even during the next few years and still more difficult to imagine how further attacks can be repelled in the future. This Socialist Government is committed to endeavouring to promote a whole-time salaried State service, and it is only the strongest pressure (the February plebiscite) which has made it decide that "the time is not ripe" and that its effort must be postponed to a more opportune time. Fresh attacks will be made at a future date by another Socialist Government or by one that is not predominantly Socialist, for we must remember that the present Act really dates back to a Coalition Government. In any case we can expect no support for our contentions from any form

of Government if we consider the widespread feeling against us on this matter in all parts of the House.

How can we hope to meet a proposed whole-time salaried State service when it is next launched if we have already sold our practices to the State? Consideration of the fact that medicine has continuously progressed in its beneficent work during many centuries, and that Governments and Ministers are ephemeral in their frets and fumes, ought to be a salutary thought for those on both sides of this controversy and a help to due perspective.—I am, etc.,

SHERBORNE, DORSET.

THOMAS MCCARTEN.

Fix Remuneration

SIR.—In a circular recently received from the London Executive Committee paragraph 3 states that payments to doctors will be made "out of a central pool . . . to be adjusted at the end of two years." There are first charges to be paid from this pool as well as from the amount paid to each individual Executive Council before the doctors can be paid. No *per capita* sum is mentioned. No Spence Committee recommendation is quoted. The doctors are to be remunerated out of the balance, whatever that may be, and even that is subject to revision.

When Lloyd George's National Health Insurance Act came into force the doctors were paid, I think, *according to* *memorandum* 13s. 6d. This was reduced to 8s. 6d. and increased to 10s. by Regulation. Are we to have the same "giggling again"? The agreed *per capita* fee should be fixed by an Act of Parliament and not reduced by the act of a Minister.—I am, etc.,

London, W. 2.

R. GALWAY MURRAY.

Alternative Service Suggested

SIR.—The long-drawn-out controversy between the present Minister of Health and the medical profession is becoming increasingly distasteful to everybody and not least to the doctors, who are being distracted from their work of healing by the exigencies of a bitter political conflict which is none of their seeking. Mr. Bevan has manoeuvred himself into a position from which it must be very difficult for him to retreat, though he can hardly blame anyone but himself for this. Is it too much to hope that even at this late hour he might prove himself to be a great statesman by setting aside party considerations and political bitterness, and by approaching the medical profession with the request that they should outline to him their ideas upon the best ways of improving the medical services of the nation?

In South Africa the profession were approached in this way, and were invited to elect a committee to draw up a plan for a national medical service. When a scheme had been produced and was approved by the profession as a whole, the Union Government, after careful examination, found it good, accepted it—and appointed the chairman of the committee Minister of Health. It sounds simple, does it not? But it was statesmanship of a high order—the sort of sound political common sense which has come to be associated with the name of Smuts.

It has long been the concern of the medical profession in Great Britain to ensure that nobody here should go short of the best kind of medical attention because of lack of means, but it has also been their concern that no rigid system should be clamped down upon the people of the country by compulsion and maintained by the threat of legal sanctions. Such a thing is utterly alien to the British way of life.

May I briefly outline a scheme which would, I am sure, meet with the approval both of the great British public and of the medical profession?

(1) The organization of hospital services over natural hospital areas centred on universities, so that these foci of research and education could influence the whole service.

(2) The extension of National Health Insurance benefit to include as of right, specialist and consultant services (domestic when necessary), diagnostic and pathological facilities, physiotherapy, and other treatment in hospitals and nursing-homes.

(3) When this had been effected and was in efficient operation, the scope of National Health Insurance to be extended to include the wives, children, and dependants of insured patients and of all other like economic status. Here it might be useful to consider raising somewhat the present income limit for admission to National Health Insurance, and, coupled with this, there should be an agreed scheme to allow "contracting out" for those who wish it—a scheme of grants in aid, for voluntary contributors, etc.

(4) Government health centres, as became possible, to be set up in the towns, and their functioning studied.

(5) A joint advisory body, with freely elected medical members, to be set up to study ways and means of improving and adding to the service as time went on and opportunity offered.

(6) The improved service to be introduced by stages, according to the money and personnel available at the time, and no attempt to be made to introduce at one leap a fully fledged comprehensive service regardless of the existence or otherwise of suitable premises, personnel, staff, medical and surgical personnel, and equipment. Failure to attempt to do so, as at present proposed by the Government, would result in as much chaos and as disastrous a failure as that which has resulted from an attack on Festung Europa launched in 1942 in response to irresponsible demands chalked upon walls to "win the second front now."

Mr. Bevan is intelligent enough to realize full well what chaos will be felt from an attempt to implement his Health Service Act on July 5, and I believe that he also knows that it will be quite impossible to give a deluded public one tithe of the gifts and benefits he has so rashly promised them. Before it is too late, then, I urge him to think again and so to reap the gratitude of a grateful nation and the enthusiastic co-operation of a great profession—I am, etc.,

A. VICTOR RUSSELL.

doctors buy and sell the goodwill of their practices instead of demanding the sole monopoly of this valuable commodity by the State.

It is very probable that Mr. Bevan will in reality be pleased at the prospect of doctors so early becoming the tenants of local authorities and living and working in council houses and prefabs as comrades of the propertyless proletariat. There is little difference between this and the health centre idea, which is primarily to make the doctor's surgery one of many rented from a local authority. The basic idea of the commonplace mind is that the masses are really very stupid and will soon believe that one doctor is just as good as another however much they may at present claim the right to choose their own doctor.

It has been held by the various medical agencies that the prestige of doctors is invariably lowered in the eyes of their patients if they are obliged to live and practice in council houses and prefabs, but as the Government have set themselves irrevocably against the buying and selling of practices this levelling down of general practitioners as a profession must inevitably follow, with disastrous effect on the recruitment of G.P.s to the new Service and the standard of service rendered.—I am, etc.,

Slough, Bucks.

N. C. HYPHER.

Payment for Work Done

SIR,—I quite agree with Mr. W. Adams, who at our last meeting described the N.H.S. as a gigantic fraud. I for my part will brook no interference between me and my private patients, whom I regard as friends. How would Mr. Bevan like it if I suggested that we reversed matters and undertook to pay each of our patients, say, 20 visits a year—no less and no more—on condition that we drew as much money as we wanted when and how we liked. We might limit it to, say, £10,000 a year. If it is fair one way it is fair the other. My own view is that if we must have a scheme it should be on the lines of the National Deposit Society, whereby the doctor marked down each item and was paid accordingly, so much a visit, etc., by the Society—i.e., paid for work done.—I am, etc.,

E. BLAKE GARLAND.

Conflicting Advice

SIR—Now that the voting is over I would wish to draw attention to one matter which appeared to me unfortunate. Taking the chair at a general meeting of practitioners in my area, among the correspondence there was read out a memorandum sent by a group of members of the Association stating that they were either members of the Council or Representatives, and advising the meeting to vote as they had done before. Whilst agreeing that a Representative has a right to express his own opinion to his constituents, I much regret that certain members of the Council should sign and agree to circulate a document the contents of which did not tally with the advice given by the Council and circulated with the plebiscite papers, unless such publication had been agreed to in Council.—I am, etc.,

PEARSE WILLIAMS.

Doctors' Houses

SIR—Dr. F. T. Wright and G. H. Rosedale (May 1, p. 855) have mentioned serious issues in their letter. I beg leave to elaborate one point, namely, the doctor's house and surgery. And this day or retire from general practice the well-known fact that of long-established doctors' houses will disappear and the doctor will have to face ever-shifting doctors' houses. This must occur if doctors are obliged to sell their houses in order to avoid Government legal action for attempting to sell goodwill with their houses. It is not likely that any sensible N.H.S. doctor will buy or build a new house and surgery and waiting-room accommodation. Nor will the Government, in its capacity as Minister of Housing will be likely to provide for G.P.s to become tenants of local authority houses and work in council houses and prefabs. The Government will have to face the fact that for the present circumstances the only way to solve the problem is to let the Government decide to let

Appeal to the Courts

SIR.—I am astonished at the decision of the Council of the British Medical Association. We should not willingly accept service under the Health Act unless we can appeal to the courts. If we are treated justly there will be no need to appeal to the courts, but the fact that we are not allowed to appeal to the courts indicates that the Minister of Health intends to treat us unjustly. If he intends to be fair he should be willing to amend the Act to allow appeal to the courts.—I am, etc.,

Liverpool.

H. E. ROAF.

Students' International Clinical Congress

SIR.—In July this year an International Clinical Congress of Medical Students—the first of its kind—is to be held in Britain under the auspices of the British Medical Students' Association. Up to date 130 delegates from 30 different countries have accepted our invitation, and a programme of lectures, visits, and ward rounds in various teaching hospitals, discussions, and entertainments for the visitors has been arranged to take place in the Universities of London, Oxford, and Birmingham.

The organizational expenses of the Congress have been met by grants from the British Medical Association and the International Union of Students. The response to invitations so far shows, however, that delegates from many countries are experiencing difficulty in meeting the necessary expense of the attendance. The British Council has generously agreed to cover the Congress fee for a number of delegates, but many countries will have to remain unrepresented unless further support is forthcoming.

May we therefore appeal through your columns for contributions from individual members of the public or from societies which have at heart the furtherance of friendship and understanding of students from all over the world, so that this important event will be truly international in character. Cheques will be gratefully received by the Treasurer, Students' International Clinical Congress, the British Medical Students' Association, B.M.A. House, Tavistock Square, London, W.C.1.—We are, etc.,

JOHN A. RYLE.

Honorary President of the Congress.

STEPHEN DRANCZ.

President of the British Medical Students' Association

HERBERT E. REISS.

London, W.C.1.

Chairman of the Congress Organizing Committee.

Temperature Records and Ovarian Activity

SIR.—Dr. Mary Barton (April 24, p. 806) has not convinced me that I should take rectal rather than oral temperatures. When I use basal temperature records to help me to determine whether a cycle is ovular or non-ovular, the "occasional deceptively low reading due to extraneous factors such as mouth-breathing" is not going to deter me unless she can produce a series of cases in which simultaneous oral and rectal temperatures have been recorded which show that the patients' mouth-

Idiosyncrasy to *d*-Tubocurarine Chloride

SIR.—We have knowledge of a case similar to the first one mentioned in the article on this subject by Drs. T. Cecil Gray and John Hulton (April 24, p. 784). We feel that the term "idiosyncrasy" is a mis-nomer in so far that it does not explain the mechanism operating. Recalling the close analogy between curare and myasthenia gravis and the great tendency of curare to lead to respiratory failure, it is reasonable to draw the inference that the action of curare is greater on the intrinsic and extrinsic respiratory musculature than on the rest of the musculature of the body.

Prof. Prescott and Organe¹ suggest and offer evidence that the hypoxia may occur when intubation is performed in a curarized patient. Prescott also stresses the initial action of curare on the brain stem, which controls vagal activity. As Organe has shown that bronchoscopy in the curarized patient does not predispose to cardiovascular failure, we are then forced to the conclusion that these deaths have their origin within the respiratory system.

The blocking of the normal neuromuscular response at the vocal nerve endings within the bronchi (Hering-Breuer reflex) by curare must exert a profound influence on the mechanism of respiration, and is closely analogous to an acute attack of myasthenia gravis, exhibiting similar symptomatology and complications. Even if we do not invoke the hypothesis of a possible bronchospasm, we have to recognize that the passage of tube or bronchoscope into air passages that are in a state of areflexia will not give rise to the expiratory effort associated with normal intubation, and we have no guarantee that the normal mechanism will return in a patient already suffering from some initial degree of respiratory obstruction which might be caused by a carcinoma of the bronchus.

It is to be noted that the second case quoted by Gray and Hulton showed no signs of respiratory obstruction and recovered. We feel therefore that the question of "idiosyncrasy" can be explained on normal physiological grounds. Furthermore, it appears to us debatable whether curare should be used in bronchoscopies if there is any evidence of respiratory obstruction.—We are, etc.,

T. HOWELL HUGHES.
D. HEWSPEAR.

Curare and Bronchial Spasm

SIR.—The use of *d*-tubocurarine chloride and thiopentone anaesthesia for bronchoscopy seems to have become a fairly well-recognized method. It has often occurred to me that the continued use in this technique of a drug which depresses the respiratory centre together with a drug which has the capacity to paralyse the respiratory muscles involves considerable danger, as it is impossible to inflate the lungs with oxygen during the procedure and the only alternative, which is to inflate the oxygen through the side tube of the bronchoscope, is far from satisfactory. In addition, most of the patients who are sent to us for bronchoscopy are in poor physical condition and are unlikely to withstand any degree of anoxia. I have used this method for some time without misfortune, but I now feel obliged to give an account of a recent experience.

A male patient, a man of 67, was admitted to hospital complaining of increasing dyspnoea, and a productive cough. His exercise tolerance was very poor and there was slight orthopnoea. Arterio-systolic blood pressure was 160/90 mm. Hg. The heart was considerably enlarged to the right. The blood pressure was 190/120. There had been some weight loss of 15 lb. He was found to have a pleural effusion on the left side and he was running an intermittent pyrexia. A diagnosis of carcinoma was suspected.

On the 11th of April, a man of 67, was admitted to hospital complaining of increasing dyspnoea, and a productive cough. His exercise tolerance was very poor and there was slight orthopnoea. Arterio-systolic blood pressure was 160/90 mm. Hg. The heart was considerably enlarged to the right. The blood pressure was 190/120. There had been some weight loss of 15 lb. He was found to have a pleural effusion on the left side and he was running an intermittent pyrexia. A diagnosis of carcinoma was suspected.

After a further 0.1 g. thiopentone had been given the bronchoscope was passed easily. All respiratory movement ceased. The thorax was compressed a few times while the surgeon withdrew the bronchoscope from the right main bronchus into the trachea. The pulse volume became weak quite suddenly and slight cyanosis developed. The bronchoscope was withdrawn and a Magill tube passed. No time was wasted during this procedure, but by the time the tube was in position the patient was grey and pulseless, and I have a vivid recollection of a grey pharynx with the cords in the cadaveric position.

The mixture of nikethamide, prostigmin, and atropine was administered easily through the Gordh needle, while continued unsuccessful attempts were made to oxygenate the patient by bag pressure from a Boyle's machine, and I wish to stress the fact that it was quite impossible to inflate the patient's lungs. No heart beat could be detected. While an attempt was being made to perform cardiac puncture one inspiratory "twitch" of the diaphragm was seen, and from that moment the lungs could be inflated easily. The pulse returned immediately with good volume, and his colour improved rapidly. The patient's first attempts at spontaneous respiration were in the form of Cheyne-Stokes respiration. He was returned to the ward 55 minutes after the commencement of anaesthesia, and oxygen was administered from a B.L.B. mask. When examined 30 minutes later a left facial palsy was detected, and all the signs of a spastic paraplegia, with increased tendon reflexes, positive Babinski, and clonus on both sides, were evident. A cerebral thrombosis was suspected. Nicotinic acid was administered intravenously and intramuscularly. By evening he had recovered almost completely. The following morning his only complaint, apart from "not feeling too good," was of slight precordial pain. All neurological signs had disappeared. He was discharged from hospital after seven days.

While there were no gross signs of cardiac failure before bronchoscopy, it is obvious from the history that the cardiac reserve was small, and it is likely that there were marked atheromatous changes in the coronary arteries. With the added effect on the myocardium of toxic absorption from the affected lung it is not surprising that a short period of anoxia was sufficient to produce cardiac failure. The cerebral changes were presumably anoxic in origin. It seems certain therefore that the dose of *d*-tubocurarine chloride should have been considerably reduced, or the use of this drug dispensed with altogether. It was, however, surprising and disturbing that even when the patient was in extremis, flaccid and grey, it was impossible to force oxygen into the lungs. I feel certain that I was dealing with a spasm of the smaller bronchioles, as at that stage no striped muscle could possibly have resisted attempts to ventilate the lungs. Whether this hypothetical spasm was due to curare or to thiopentone, or to some other factor, I am not competent to judge.—I am, etc.,

Manchester,

MICHAEL M. BOYLE.

Erythroblastosis and Kernicterus

SIR.—The annotation on erythroblastosis and kernicterus (May 1, p. 843) must not pass without comment lest it be assumed by readers not engaged in this work that the theories there outlined are founded on accepted facts. Surely the annotation is wrong in stating that the staining of nerve cells causes their degeneration. It is generally accepted that the sequence of events is, first, damage to and degeneration of the nerve cells and, secondly, icteric staining of the damaged nerve tissue by circulating pigment; this is entirely analogous to the coloration of cerebral lesions by vital staining in experimental animals.

The hypothesis that the different clinical varieties of haemolytic disease are explicable on the grounds of differences in the quality of the maternal iso-antibodies is not borne out by a study of a large series of cases. In my experience the type of foetal disease cannot be predicted with certainty by determination of the quality of the maternal antibodies. The most that can be said is that a high titre of blocking antibodies is likely to be associated with hydrops foetalis and still-birth. In a recent publication on this subject I gave illustrative case histories in which the lack of correspondence between type of antibody and foetal disease is clearly shown (Cappell, 1947).

Wiener's theory that icterus gravis neonatorum is due solely to anti-Rh agglutinins which are "milked into the foetal circulation in the course of labour" is a piece of arm-chair philosophy which is accepted by no competent pathologist experienced in this work (cf. Potter, 1947). If it were true it would be possible to prevent icterus gravis by caesarean birth

—a possibility unfortunately abundantly refuted by experience. The statement that the changes of *icterus gravis* are due to agglutinative thrombi in the vessels of liver, bone marrow, and brain is only an attractive speculation which is, unfortunately, divorced from reality and is in direct conflict with all the morbid anatomy of the disease. The post-mortem appearances provide unmistakable evidence of long-continued pre-natal haemolysis, and the extra-mullary haemopoiesis which is so conspicuous a feature of many cases cannot conceivably have developed only after birth.

In conclusion I can only agree with the last sentence of your annotation, but this is just what the American writers cited have failed to do; instead they have promulgated a theory based on pure speculation without a shred of clinical or pathological evidence to support it.—I am, etc.

The University, Glasgow

Iridocyclitis Treated with Benadryl

SIR—I found the letters of Dr. Bernard Shaw (Feb. 7, p. 275) and Dr. J. Moss (Feb. 21, p. 367) on this subject interesting. A parent of mine here, an ex-naval officer, has had recurrent attacks of iridocyclitis for many years and has seen several specialists in addition to many general practitioners.

The condition always occurred at night, and he died from the service in submarines during the Kaiser's war. He always referred to it as "periscope eye." I usually refused a morphine and heard that the various specialists have advised a varied range of treatment, from arsenicals and period to period, irrigation, prostatic massage, and injections of milk. Last year he had an attack which I treated for a short time with sulphur, iodine, but as there was no obvious response I put him on to injections of "acetylarsan" and emetine. This attack lasted for 12 days and was the shortest he had had then.

This month he surprised us all by a fresh attack, but in the left eye for the first time on record, which rather upset the periscope analogy. I was afraid that occurring in a new eye it might be more severe than before, but I treated it with atropine and hot spoon bathing as before, emetine and acetylarsan, and "benadryl" in addition. This attack is the shortest he has had, and he was clear in one day this time. I cannot say for certain whether the benadryl actually shortened the time, but its soothing and soporific effect was a great help and the patient appreciated it very much.

The rationale of emetine is that he has suffered in the past from dysentery, and in this colony a great percentage of people sooner or later suffer from chronic amoebiasis and require emetine periodically.—I am, etc.,

Nairobi, Kenya Colony.

G. DUNDERDALE.

Barium Enema and Acute Intussusception

SIR—Drs. Brenda Morrison and Donald Court are to be congratulated on their excellent account of "Acute Intussusception in Childhood" (April 24, p. 776), but as stated in the annotation (p. 794) "some may differ from them" on their attitude to barium enemata as an aid to diagnosis and as a method of treatment.

As quoted by Morrison and Court, the papers by Nordentoft, Nyberg, and Hipsley¹ show that the barium enema can be of great value both in diagnosis and treatment of early acute intussusception.

In two such cases which I saw as surgical registrar at the King George Hospital, Ilford, barium enemata were found to be of value.

Case 1. A well-nourished baby boy, aged 7 months, was admitted 14 to 15 hours after the onset of what seemed to be spasmodic abdominal pain. There was no vomiting, nor was there any blood detected on rectal examination; while the abdomen, though carefully palpated, held no definite lump.

An enema was slowly administered, under anaesthesia, using a very thin mixture of barium; the progress of the barium was followed by viewing with a screen, and the invaginated loop of ileum was clearly seen to "unfold" itself as far as the ileocaecal junction, when the ileum seemed to "jerk" itself back to its normal position. Two days later the child was home, fully recovered.

Case 2. This child was also suspected of having an early (18 hours) acute intussusception, but again the signs were not sufficient to warrant operation. A barium enema confirmed the diagnosis,

and also appeared to reduce the intussusception, though no "jerk" was seen. In this case, however, pain and vomiting recurred after a short interval, and at laparotomy an early ileocaecal intussusception was found. Reduction in the usual way was followed by uneventful recovery.

These cases illustrate how a barium enema can be of value in diagnosis in the early stages of intussusception, and when the picture is not presented. In Case 1 it was of obvious value as a mode of treatment. Though a failure as treatment in Case 2, the diagnosis was confirmed and no harm resulted.

In this way early cases can be diagnosed, instead of being allowed to become late cases by the "wait and watch" method of observation; whilst in addition to the diagnosis being made the condition may be cured at the same time—thus making operation unnecessary. According to Babcock, 60% of intussusceptions are reducible in the first 24 hours, on hydrostatic pressure—I am, etc.,

Late News

SIR—Being a weekly reader of the *Journal* I am sure, reading a week and more behindhand, you made it none the less important to members. This delay is added to when the *B.M.J.* is delivered by post till Monday or Tuesday, and then the day's delay press gets in first with the news. The importance of news which reaches client or patient, and then the doctor to whom in these anxious days it may be of great importance. What has taken place at Council or B.M.J. meetings, or at local meetings, or what entered into the *Journal* department, he gets late perhaps after the event.

Members, being a daily scattered, find it hard to get the *Journal* for ungarbled facts for which they are entitled. In these days, when things move so fast, it is a pity that a column or part of one be given in the *Journal* to the members, and it seems greater in importance than ever before. The "Late News" Summary, framed by the *Journal* department of the Association under the watchful eye of the Editor, thus to publish happenings from local as well. Headquarters sources.—I am, etc.,

S. W. TOWN SMITH

Association of Medical Record Officers

SIR—The need to improve the technique of medical record keeping has frequently been a subject of discussion but until comparatively recently little organized action has been taken. What is recognized that the standard of clinical records is and must remain a medical responsibility, it is thought that this responsibility could be lightened, and medical time and expense saved, by the provision of trained lay assistants. With this end in view an Association of Medical Record Officers has now been inaugurated and it is felt that the medical profession will give their co-operation and guidance whenever it is sought, as they have always done in such matters in the past. Two of the Association's aims are:

(1) To promote the development of techniques in medical record keeping, to diffuse among the members and others all information and technical and general knowledge from time to time available regarding the keeping of medical records or of use in connexion therewith.

(2) To provide opportunities by means of lectures, discussions, or other intercourse among the members for the exchange of information and opinions regarding the method, processes, and technique of medical record keeping.

Training courses for lay personnel already responsible for medical records are being organized in several of the Regions as an interim measure preparatory to a more comprehensive scheme of training. Records officers interested in these training courses and in membership of the Association are invited to get in touch with the honorary secretary.—We are, etc.,

B. BENJAMIN,

Statistician, Public Health Department,
London County Council (Chairman of Council)

ELSIE FOYLE,

Records Officer, Christie Hospital and Holt
Radium Institute, Watford Road,
Manchester, 20 (Hon. Secretary).

POINTS FROM LETTERS

Holidays Patients

Dr. P. LEONARD LEY (Great Yarmouth) writes: I am well aware that neither the Government nor the B.M.A. Council has the time or the knowledge to consider details under the New Health Act. A real problem has just occurred to me. How are doctors at seaside resorts expected to deal with the doubled populations presented to them during the holiday months?

New Act Necessary

Dr. A. R. EATON (London, S.W.3) writes: . . . Do please demand something up of the Act for five years, during which we might be called upon to help the Government to evolve something good, and avoid the notion, and avoid the eternal disgrace of being accessory before the fact of the introduction of a scheme which will certainly not be a new Act is absolutely necessary.

British Medical Libraries

Mr. ALFRED L. GOODALL (Hon. Librarian, R.F.P.S., Glasgow) writes: I was very interested to read the article of Mr. W. R. Le Fanu on "British Medical Libraries" (April 24, p. 798). I write to call attention to a library which Mr. Le Fanu does not mention—that of the Royal Faculty of Physicians and Surgeons of Glasgow. In its historical section this collection is in many ways unique and worthy of an important place in British medical libraries.

In current periodical literature we subscribe to over 180 journals, including many not easily obtainable elsewhere in Britain. It is available to Fellows of the Royal Faculty, to postgraduate students, and to members of the Royal Medico-Chirurgical Society of Glasgow. In association with the Royal Society of Medicine our collection is available to all research workers, and we have a microfilm reader making the world literature easily reached through the Royal Society of Medicine or the Surgeon-General's Library.

Ambiguity of Act

Dr. J. W. BARNETT (London, S.W.7) writes: . . . We must insist, and keep the B.M.A. up to it, that all amendments (not concessions) proposed by the B.M.A. should be accepted. In addition all clauses of the Act should be further examined and amended to ensure removal of the ingenious and deliberate ambiguity which is such a feature of the Act and allows the Minister full scope to adjust it as he likes and when it suits him. Even when all the amendments are accepted, operation of the Act should be postponed till the Minister has provided at least part of the tools for the job—i.e., extra hospitals, beds, and nursing and domestic staff. Without these essentials the Act must fail in operation, and well the Minister knows it. He also knows that he will have to explain its failure to Parliament and the people. That is easy. He has insulted and deceived the medical profession and refused all amendments, and of course the wicked doctors who decline to work an Act will be made the scapegoats. . . .

Penal, Carcinoma

Dr. G. P. CHARLWOOD (Johannesburg) writes: I was interested to read Mr. W. Sampson Handley's letter (Dec. 20, 1947, p. 1050) and the subsequent correspondence. I saw seven cases of carcinoma of the penis in India. In every one the prepuce was loaded with cancer. In none had the patient ever drawn back his prepuce. Circumcision should certainly be performed for those who prefer to work with it.

Representation of Profession

Dr. C. HOWARD WATSON (Sheffield) writes: At a Group meeting in Sheffield recently the recent development in the situation caused by the Minister's offer to introduce an Amending Bill was discussed. Much alarm was caused by Lord Moran's speech in the House of Lords in reply. What authority or right has Lord Moran to say that any reasonable doctor should accept the terms and now expect him to make the Act a success? Lord Moran, eminent as he may be, does not represent the profession, and particularly the general practitioners. . . . The meeting also expressed the opinion that the Council should be urged to stand out firmly for the retention of the current and past standards of practices. This principle is of far more importance than any of the others, and on this principle the interests of the patient and the liberty of the doctor depend.

Carbon Monoxide and Cancer

Dr. J. W. FRANK (Manchester) writes: It is a striking fact that the production of cancer in experimental animals is associated with the production of a focus of carbon monoxide in the lungs. If carbon monoxide is the end product of the process, then the production of cancer in any part of the body outstrip the production of cancer in the lungs. It is therefore of interest to note that the production of cancer in the lungs is associated with the production of carbon monoxide in the lungs.

Obituary

PROF. A. H. BURGESS, M.Sc., F.R.C.S., LL.D.

We announce with regret the death of Prof. A. H. Burgess, who was for many years Professor of Clinical Surgery in the University of Manchester. Prof. Burgess died suddenly, at the age of 74, on May 6 in Edinburgh, where he was attending the annual conference of the Association of Surgeons of Great Britain and Ireland, of which he was at one time President. In 1929 he was President of the British Medical Association.

Arthur Henry Burgess was born at Shelford, Lancashire, on Feb. 2, 1874. After leaving school he spent a year in a shipping house in Manchester before entering Owens College, where he graduated B.Sc. in zoology in 1892. In this same year he won the Dauntsey entrance scholarship in medicine and was the Dalton Natural History prizeman. He was awarded the junior and senior Platt Exhibitions in Physiology in the next two years. Burgess continued with his work in zoology and took the M.Sc. in 1895. A year previously he had also won the Victoria University scholarship in medicine. He took all the medals for class examinations, and concluded his brilliant undergraduate career with the Turner Medical and Dumville Surgical Prizes for 1896.

[F. W. Schmidt]

the year when he graduated M.B., Ch.B. with first-class honours. The conjoint examination Burgess took in his stride at the same time. Resident surgical posts in the Manchester Royal Infirmary, the Royal Children's Hospital, and Crumpsall Municipal Hospital followed over the next few years, and he took the F.R.C.S. in 1899. He was then appointed visiting surgeon to the Crumpsall Hospital, and honorary surgeon to the Children's Hospital and to the Christie Cancer Hospital.

Burgess introduced modern methods in the practice of surgery in Manchester. He was taught to operate in a long apron with a bib held by tapes round the neck, with rolled-up sleeves and ungloved hands. He adopted at Crumpsall the all-enveloping white overall with a gap only for the eyes. This was such an innovation that a cartoon appeared in the students' *Gazette* showing Dr. E. S. Reynolds, then medical superintendent of the hospital, gazing in mild surprise at this apparition. Burgess was also depicted holding a cystoscope half as long as his own tall self, for he was the first surgeon in the city to become proficient in the use of this instrument. He also gave special attention to intestinal surgery in the days of Murphy's button and Senn's decalcified bone plates, experimenting on the cadaver with various methods applied to a gut which he had dissected out, filled with water, and suspended from a height in order to produce the required pressure. Burgess was one of the early operators for acute appendicitis, and impressed the Manchester Medical Society at one of its meetings in 1907 by showing four specimens that he had removed that day: in each of these cases the appendix was gangrenous. In 1912, in a paper published in the *Journal*, he analysed 500 consecutive cases operated on for acute appendicitis.

Elected honorary assistant surgeon at the Royal Infirmary in 1905, Burgess continued in active work there until 1934, when he retired on reaching the age of 60. His last appearance as a member of the active staff took the form of a clinical round on S5, which was attended by many of his colleagues and a score of his former house-surgeons.

Burgess soon became well known as the leading young surgeon in Lancashire and built up a large consulting and operative practice. Tall and spare in build, he was no dawdler over his work, as the elderly accident-room nurse found when

Dr. ERNEST MAURICE FRAENKEL died on April 20 after a short illness. Dr. Fraenkel was educated at the Universities of Breslau, Munich, and Freiburg. He had been a professor of medicine in the University of Berlin, and was on the staff of the University Clinic, the Charité Hospital, and the Rudolf Virchow Hospital there. Like many other physicians he came to this country in 1932 since it was impossible for him to continue his work in Germany. He was first of all at the Westminster Hospital as a John Proffit research worker. Most of his work at this time was concerned with the Rous carcinoma and with the filtrability of the tubercle bacillus. He took the L.M.S.S.A. in London in 1936, and shortly afterwards was working at the L.C.C. laboratories on the significance of moulds in certain cases of asthma. He was naturalized in 1940, and during the war was in practice in Buxton. On his return to London in 1945 he was made consulting allergist to the L.C.C., and published a number of papers in this and other journals on allergy, bronchial asthma, and related subjects. He was a physician with a philosophic outlook, and some of his ideas were held to be in advance of his time. The sympathy of those who knew him will be extended to his wife and to his daughter.

NATIONAL HEALTH SERVICE

Mr. BEVAN repeated his statement of April 15 that Circular 3/48 did not "indefinitely postpone" all provision of health centres. Some local health authorities were already preparing proposals for providing health centres in accordance with the guidance given in the Circular. He did not understand the reference to "alternative accommodation."

Alien Practitioners

Mr. BEVAN answered that registration was conditional on residence in the United Kingdom. These practitioners could

Where do you find athlete's foot?

Users of communal swimming pools can be protected against this wide-spread infection by the use of 'Mycil', the new fungicide — *p*-chlorophenyl- α -glycerol ether — developed in the B.D.H. Research Department.

'Mycil' is effective both in prevention and treatment and is conveniently presented as 'Mycil' Ointment and 'Mycil' Dusting Powder. Descriptive literature on request.

Rutin in Capillary fragility

Rutin is a crystalline glycoside obtained from the leaves and flowers of buckwheat. Recent reports attribute to Rutin the property of reducing capillary fragility when this is abnormally raised.

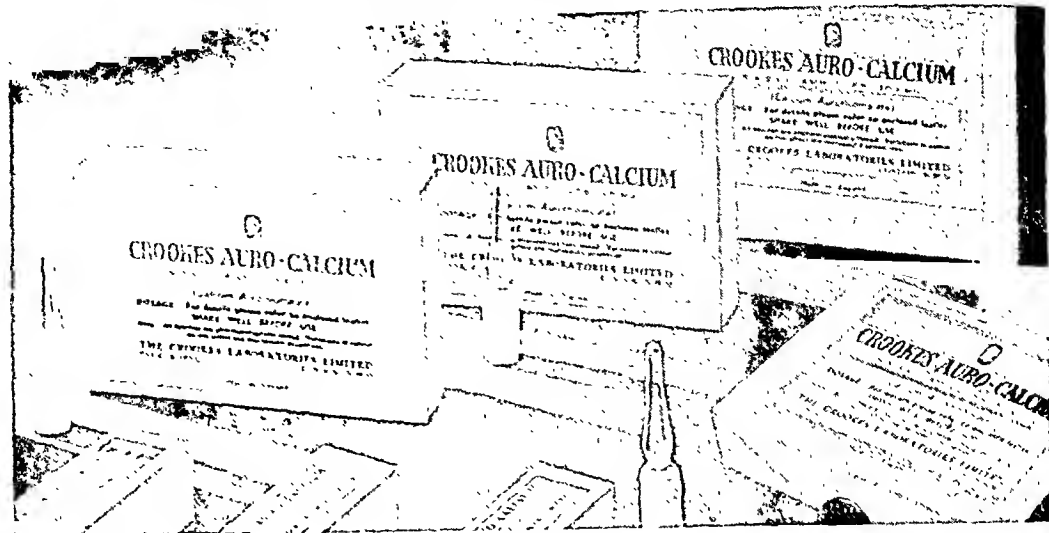

In our research laboratories a limited quantity has been isolated from buckwheat grown in this country and is available in the form of tablets.

Rutin A & H is suggested for administration in haemorrhagic conditions due to increased capillary fragility or permeability, especially when this condition is associated with hypertension, nutritional deficiency or toxic effects of drugs.

Literature and price on application.

Notes.—(1) Rates for 1938 are based on civilian and non-civilian data and for 1939, 1945, and 1946, on civilian data only.

(2) Rates for notifiable diseases for 1938 and 1939 are based on original notifications; those for 1945 and 1946 are based on original notifications corrected for later amendments of diagnosis.

(3) The number of cases of whooping-cough and measles in 1938 and 1939 is not available. Notification of these diseases was not compulsory until 1944.

not be registered under the Act while serving abroad. If they subsequently took up residence it would be open to them to apply.

Deaths from Notifiable Diseases

Mr. SKEFFINGTON-LODGE requested on April 29 figures showing the trends in regard to the death rate and the chief notifiable diseases, compared with the most satisfactory statistics for pre-war years.

In reply Mr. BEVAN furnished the above tables.

Position of Assistants

On May 6 Mr. BOWDEN asked the Minister of Health if a doctor now employed as an assistant could on July 5 commence a separate practice from his principal, providing patients wished to be placed on his panel and the district was not considered to be over-doctored, or must he commence outside of the area in which he was now practising as an assistant?

Mr. BEVAN said that with the agreement of the Medical Practices Committee an assistant could on or after July 5 practise as a principal in any area under the National Health Service, but the agreement of the Committee would not relieve him from any restrictions imposed by any personal legal agreement previously entered into with his principal.

Doctors' Wives

Sir WALDRON SMITHERS on May 6 asked whether Mr. Bevan had studied details which had been sent him about the position of doctors' wives under the Health Act. Mr. CUTHBERT asked what answer the Minister of Health had given to the request by the League of Doctors' Wives asking him to postpone the introduction of the National Health Act until he had the necessary buildings, equipment, and trained personnel. Sir JOHN MELLOR asked whether Mr. Bevan would provide assistance for those doctors for whom, and for whose households, the National Health Service would cause increased secretarial work, telephone attendance, and aggravate domestic disturbance.

In reply to the three questions Mr. BEVAN said that, as he had told those concerned, he thought there was a tendency to overestimate the effect of the new Service upon the position of doctors' wives. In any case he did not believe that they on reflection would wish to deprive the rest of the community of the benefits of the scheme by postponing the appointed day.

In reply to a further question Mr. BEVAN said that if it was found that extra work was thrown on doctors' wives and they found it burdensome, the Government would consider what help it could give in the provision of domestic service. He reminded Members that there were other wives with onerous burdens as well as doctors' wives.

Cost of the Service

Mr. ODEY on May 6 asked why the new Health Service information leaflet did not state the weekly cost of the stamp contribution. Mr. BEVAN said the National Health Service was

not dependent on a stamp contribution, which was a matter for National Insurance.

Mr. ODEY asked for an assurance that Mr. Bevan was not influenced by the fact that much of the new Health Service would not be available for twenty years. Mr. BEVAN said that in every part of the world there must be limitations on health services because of their dependence on the medical and physical resources available. If, as Members asserted, the Ministry would be unable to give the service, then, obviously, there would be no cost. The cost of the service which the Ministry was able to give was borne from the National Exchequer and not from insurance contributions.

Col. STODDART SCOTT asked whether Mr. Bevan said the £200,000,000 which the Health Service would cost was coming entirely from rates and taxes with nothing out of the weekly contributions.

Mr. BEVAN replied that it would come almost entirely from the Exchequer and the rates.

Col. STODDART SCOTT: The right honourable gentleman says "Almost."

DENTAL SERVICES

Sir HUGH LUCAS-TOOTH moved on May 5 that the National Health Service (General Dental Services) Regulations, 1948, dated March 12, be annulled. At the start of the debate Sir Hugh asked that the sitting be suspended owing to the absence of a Minister to reply.

Passing to the Regulations he said that under Subsection 1 of Section 40 in the National Health Service Act, 1946, councils for counties and county boroughs were to arrange with dentists for providing services at a health centre or otherwise. Under Subsection 2 the Minister was to make Regulations carrying out that general intention. The Regulations would deal with the preparation and publication of lists of would-be practitioners in the dental service and would leave it open to every dentist to say whether he wished to come into the scheme. The Regulations were to confer the right on any person to choose his own dentist and to establish a Dental Estimates Board for approving estimates of the cost of treatment. This Section had not been amended in its passage through Parliament.

The White Paper which had been published with the Act stated that dentists would normally be able to start treatment without further reference and subsequently to submit a claim for payment from public funds. Since the Act became law discussion had gone on between the dentists and the Ministry, but there appeared to be a complete breakdown in the negotiations. Two main points were the question of clinical freedom and the question of remuneration. The Minister insisted that the remuneration of dentists should be by fixed fees; the provisions on the subject in the Regulations were wholly the responsibility of the Minister. At this point Mr. Bevan entered the House.

Proceeding, Sir Hugh said that dentists practising in private surgeries would have to send their estimates to the Dental

Estimates Board. All estimates for dental treatment for the whole country whether requiring prior approval or not had to go to a single board of a chairman and eight members. Estimates were divided into those which could be completed without obtaining the approval of the Dental Estimates Board and those requiring prior approval. He was informed that 75 per cent of the work of the dentist fell in the second class. Sir HUGH estimated that in an ordinary practice at least two out of three would require prior approval. There were twelve hundred practising dentists, so something like 150,000 prior approvals would have to be given weekly.

Blood and Vulcanite

One member from the Spens Committee had not yet reported. The Populations stated in effect that every dentist would be paid a single flat rate for each item of treatment whatever his skill or experience. If a low basic rate was paid without regard to skill, the better dentist would stay out and the only one who came into the scheme would be those rudely labelled as the "blood and vulcanite" type. He suggested there should be a classification with a higher rate of charge and the dentists could choose into which classification they went.

SIR WAVELL WAKEFIELD felt there had been discourtesy and there was a strong feeling of dissatisfaction at what had taken place.

MR BEVAN said that was the second or third time that the representatives of some part of the medical profession had made this statement. If it was repeated he would publish the verbatim report of the exchanges between him and representatives of the medical profession. All these conversations had been confidential and he was quite helpless when a stupid statement like that of Sir Wavell's was made.

SIR WAVELL WAKEFIELD said he was making a statement of the dental profession felt.

MR BEVAN. It is untrue.

SIR WAVELL WAKEFIELD said Mr. Bevan referred to the medical profession but that he had spoken of the dental profession. He asked Mr. Bevan what were his intentions about dental work which was done by independent qualified dental technicians. He pointed to the provision in the Regulations that as a condition of obtaining general dental services a person should, as required by the Board, submit himself to examination by a dental officer. He thought those words reflected on the professional skill of the dentist. He asked whether members of the Dental Estimates Board would be full-time or part-time members of the Board and for what period they would be appointed.

No Plebiscite

MR BURN, said the great mass of dentists did not wish to submit themselves until they knew what remuneration they could get. To say that they opposed the scheme was nonsense. Up to the present there had been no plebiscite and no democratic method of judging their views. If there was to be a National Health Service there must be a Dental Estimates Board to adjudicate between patients and dentists and between the Government and the dentists. The great mass of cases would go through the Board without any need for professional opinion at all. The Minister had followed almost word for word the suggestions of the British Dental Association of what should require prior approval. When he himself had suggested that Schedule A should include crowns and inlays, members of the Control Committee of the Dental Profession turned down the suggestion because they believed some members of the profession were not capable of carrying out all types of crowns and inlays without prior approval. When more skilled work required prior approval by the Dental Estimates Board there could be a varying fee for each item.

MR BURNES said the Regulation embodied all the worst fears of what would happen to a professional service when the Government took hold of it.

D. H. B. MORAN, referring to the Second Schedule, said that he was first of all that the removal of infected teeth and the removal of infected treatment and reference to the Dental Estimates Board was one that very few fractured jaws could be treated. It seemed unnecessary to include fractured jaws in the list of cases which would not receive emergency treatment.

Government Reply

MR BEVAN, in reply to the debate, said the Regulations would set a standard of service and Mr. Bevan was not going to set a first-class standard of service. He was going to set a standard of service for the general health. He did not think that the Government would be mainly paid for out of the pocket of the patient. He would like to reduce to a

minimum the intervention of the Dental Estimates Board. There was a striking similarity between the proposals in the Regulations and those advocated by the profession early in 1946. The Minister had indicated his view that in ordinary cases the reply of the Estimates Board would come back within a week. The Board would not see every estimate and pass it. Its job was to supervise a large staff which would deal with these estimates, the majority of which would be capable of being dealt with by means of rules.

He did not know any answer to the problem of special payment for the man who was doing particularly good work and he would be glad to hear further views on the point. Regarding shops for the repair of dentures the Ministry intended that they should not be included in the service. All repairs under the National Health Service would be under the supervision of dentists. It was not the intention of the Government to put any financial limit on expenditure, other than the limits laid down in the Regulations. It desired that whatever was clinically necessary should be done. Dentists had not, at the moment, been asked to join the scheme. The Regulations had been tabled because the Government felt that they should be discussed. The wording of the Second Schedule had been prepared in consultation with the profession. An x-ray examination which cost more than two guineas but was urgent would not necessarily have to go to the Dental Estimates Board.

On a Division the Regulations were approved by 147 votes to 45.

Air Ambulances

Answering in the House of Lords on April 27 questions by Lord FAIRFAN OF CAMERON on the provision of air ambulance services from islands off the coast of Great Britain, Lord NATHAN said that at present county councils in Scotland were responsible for air ambulance services but that the Department of Health for Scotland would assume this responsibility on July 5. He was taking steps to secure and extend the provision by British European Airways of adequate ambulance services to islands off the coast of Great Britain. These services, however, depended upon the provision of adequate landing grounds, and that provision was not the responsibility of the Ministry of Civil Aviation but of the health departments or local authorities. Air ambulances were at present available to Islay, Tiree, Barra, Benbecula, Stornoway, Orkneys and Shetlands, South Harris, North Uist, Isle of Man, Scilly Isles, Alderney, Jersey, and Guernsey. Consideration was being given to extension of the service to the islands of Mull, Coll, Colonsay, Fair Isle, and Foula.

British European Airways used D.H. Rapides, which could be quickly converted into air ambulances. The Rapides in Scotland were based on Renfrew and Aberdeen, and those for services off the English coast from bases at Speke, Land's End, and Jersey. In addition the Royal Air Force had two aircraft fitted as air ambulances for the movement of sick Service personnel. These could also be used in emergency to transport civilians. The numbers conveyed from the Scottish islands were 94 cases in 1945; 146 cases in 1946; and in 1947, 168 cases. An air ambulance could be summoned by telephone or telegraph by any doctor whose name was in the list supplied to the British European Airways Corporation by the Department of Health for Scotland. A recent failure to convey two patients from the Island of Westray occurred because the air strip there was insufficient for the safe operation of a D.H. Rapide.

Industrial Injuries.—The National Insurance (Industrial Injuries) Bill which was published on April 30 is designed to forestall difficulties which further study of Section 14 of the National Insurance (Industrial Injuries) Act, 1946, has shown may occur. This section provides a special hardship allowance to an industrial pensioner who by reason of his injury is likely to be permanently unable to return to his old job and for the time being unable to follow employment of an equivalent standard. With recent advances in rehabilitation, doctors may be reluctant to say that a man would never be fit again for his regular occupation. The Bill will therefore authorize the payment of the allowance of 11s. 3d. a week while measures of rehabilitation are being tried.

Overproduction of German Doctors.—Replying on May 3 to Mr. SOUFREVILLE HASTINGS, Mr. MAYHEW said certain universities in the British Zone last year offered to take a number of students who claimed to have been refused admission to Berlin University, providing they did not count against the maximum strengths laid down for their medical faculties. The Control Commission could not approve this, as to do so would go directly counter to their policy of preventing the overproduction of men and women for the medical profession, which was already overcrowded. The students must therefore take their chance of acceptance by the Zonal universities in competition with other candidates for places within the permitted strengths of the faculties.

No. 17

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended April 24.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland. Figures of Births and Deaths recorded under each infectious disease, are for: (a) The 125 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland. A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1948					1947 (Corresponding Week)

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county) and Northern Ireland.

§ Polymyositis and polio-encephalitis for England and Wales are combined.

|| In England and Wales and Eire.

EPIDEMIOLOGICAL NOTES

Inoculation against Plague and Typhus in International Quarantine Practice

The World Health Organization Expert Committee on International Epidemic Control decided on April 17 to ask the Executive Secretary of the Interim Commission of W.H.O. to make known to National Health authorities the following: "The Committee strongly emphasized the fact that, whatever its value as a measure of individual protection within the area of a plague epidemic, anti-plague vaccination had no place as a quarantine measure in the international control of the disease"; also "the Committee was strongly of opinion that vaccination against typhus, although it conferred considerable protection to the individual, was not justified as an international quarantine measure." The Committee agreed that the use of insecticides with a residual action should be the chief measure of international action against these diseases.

These views coincide with those expressed on Oct. 16, 1947, by the W.H.O. Expert Committee on Quarantine—views which, endorsed by the Interim Commission, read as follows: "The Committee stressed the fact that inoculation against plague or typhus cannot be required under existing Conventions, and observed that such measures had little value for the protection of countries receiving travellers from infected areas. In its opinion disinsection of the travellers and their belongings by means of D.D.T. or other efficient insecticides would be more efficacious in preventing the importation of these diseases."

Quarterly Return for England and Wales

The Registrar-General's Quarterly Return for the quarter ended Dec. 31, 1947, was published on May 13. The infant mortality rate was 39 per thousand related live births. This was the lowest rate ever recorded for a fourth quarter in this country, being 4 per thousand below that for the fourth quarter of 1946 and 10 per thousand below the average rate for the fourth quarters of the ten preceding years. The birth rate in England and Wales during this fourth quarter of 1947 was 17.8 per thousand compared with an average rate of 15.2 for the fourth quarters of the five years, 1941-5. Stillbirths represented 2.4 per thousand total live and stillbirths, which is 3.4 lower than the rate for the fourth quarter of 1946. The death rate was 11.0 compared with 11.3 for the corresponding quarter of 1946 and an average of 11.5 for the fourth quarter of 1941-5. There were no cases of smallpox notified and no deaths from smallpox registered during the quarter.

Discussion of Table

In England and Wales the chief features of the returns were the large rises in the notifications of dysentery 142 and diphtheria 43. An increased incidence was also recorded for scarlet fever 245, while a decrease was reported in the incidence of measles 589 and of whooping-cough 161.

The decline in the notifications of measles occurred mainly in the counties surrounding London: in the north there was an increase. The largest falls were London 213, Essex 76, Middlesex 70, Kent 62; the largest rises were Durham 164, Lancashire 130, Warwickshire 116.

A rise in the incidence of scarlet fever was recorded in most areas except the south-eastern and south-western regions, where a fall of 28 occurred; the largest rises were Lancashire 60 and London 37. The largest variations in the trends of diphtheria were increases of 18 in Lancashire, due to the experience of the county boroughs, and of 12 in Yorkshire West Riding, due to a heightened incidence in the rural districts. The largest changes in the returns of whooping-cough were an increase of 54 in Warwickshire and a decrease of 52 in Lancashire.

A series of fresh outbreaks of dysentery was responsible for the large increase in the notifications of this disease, which reached the highest total for two years. The new outbreaks included Derbyshire, Chesterfield M.B. 68; Sussex, Hastings C.B. 36; London, Kensington 16; Durham, Sedgfield R.D. 12; Middlesex, Tottenham M.B. 11. The other large returns of dysentery were Yorkshire West Riding 39 (Sheffield C.B. 24) and Lancashire 35 (Oldham C.B. 8, Whiston R.D. 8).

In Scotland infectious diseases were slightly less prevalent during the week. The largest falls in incidence were dysentery 31, measles 19, and diphtheria 11. The returns for dysentery were the lowest for five months and the total for diphtheria was the lowest for four months.

In Eire the notifications of measles rose by 21, while the notifications of whooping-cough fell by 13. The rise in the incidence of measles was fairly general throughout the country, excluding the county boroughs, for which a slight fall was recorded.

In Northern Ireland only small variations in the totals of notifications were recorded. The notifications of scarlet fever declined by 11 in the county boroughs but rose by 8 in the remainder of the country.

Week Ending May 1

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,538, whooping-cough 1,654, diphtheria 134, measles 10,169, acute pneumonia 546, enteric fever 57, acute poliomyelitis 13, dysentery 119, paratyphoid 3, and typhoid 12.

Medical News

Lapley Memorial Prize

The Lapley Memorial Prize, value £21, is open to competition for officers of the Colonial Medical Service who are serving, or who have served, in West Africa. The prize will be awarded for the best paper submitted on a topic falling within one of the following subjects (special consideration being given to original work): (a) tropical medicine or surgery; (b) tropical hygiene and sanitation; (c) tropical entomology and parasitology. Papers, which may consist of either published or unpublished work, should reach the Assistant Dean, London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1, by Oct. 1.

Oliver Memorial Fund Award

Dr. R. R. Race, director of the Medical Research Council's Blood Group Research Unit, is this year's recipient of the Award of £50 by the Oliver Memorial Fund for Blood Transfusion for his researches into blood groups. The honorary treasurer of the fund (Mr. I. W. Mills, National Provincial Bank, Ltd., Holborn Circus, London, E.C.1) informs us that a similar amount will be awarded next year.

Alleged Cancer Cure

A committee appointed by the Australian Government to inquire into an alleged cure for cancer advocated by Mr. John Braund, a dentist of Sydney, has found that it amounts to an outstanding public mischief. The committee said that the treatment included injections of alum, and that in no case it had investigated had Mr. Braund proved to them that he could cure cancer.

Awards for Cancer Research

The David Anderson-Berry Prizes for 1947 have been awarded to Dr. P. C. Koller, of the Royal Cancer Hospital, London, and Dr. Paterson Paterson, Director of the Holt Radium Institute, Manchester. Prof. Sir William Wright Smith, President of the Royal Society of Edinburgh, presented the prizes on May 3. Dr. Koller's award was for his work on the effect of irradiating tissues with radium, and Dr. Paterson's for his contributions to determining radioactivity.

British Schools Exploring Society

The North and Quebec Expedition, leaving on Aug. 4 and returning on Sept. 25, needs an honorary physician and an honorary surgeon. Applications are invited for these posts. The entire cost to each member will be £130 plus about £10 10s. for personal equipment. Applicants should apply as soon as possible to the honorary secretary, White House, Old Oxted, Surrey, if possible suggesting a day when they could come up to London for an interview.

The Almoner

The Hospital Almoners' Association first published a *Year Book* in 1924. In 1947 the *Year Book* was replaced by a small quarterly *Almoner*. The Institute of Almoners, with which the Association is affiliated, has now published the first issue of a monthly journal, *The Almoner*. This includes messages from Sir Wilson Paterson and Sir Alfred Howitt, the President of the Institute, a selection of short articles and a review by Prof. Alan Howitt of the interim report of the Royal College of Physicians on the practice of social and preventive medicine. The price of the journal is 6d., and copies may be obtained from the Institute of Almoners at Tavistock House (North), Tavistock Square, London, W.C.1.

NHS Superannuation Scheme

The Ministry of Health has issued a pamphlet entitled "Superannuation Scheme for the National Health Service." It is an explanatory booklet for the superannuation scheme and contains details of the scheme and a list of the members of the scheme.

Imported Food Amendment Regulations

The Minister of Health and the Minister of Food have jointly made Regulations amending the Public Health (Imported Food) Regulations 1937 to allow the importation of mutton and lamb carcasses from which a lymphatic gland has been removed. The amendment will bring the Regulations into line with present-day practice in exporting countries.

Joint Tuberculosis Council

The main subject considered at the February meeting of the Joint Tuberculosis Council was the action of various Regional Hospital Boards in deputing the overseeing of regional tuberculosis work to medical officers charged with other duties. An instance was mentioned of the appointment of a medical officer in one region to supervise infectious-disease hospitals as well as the tuberculosis service, and also an advertisement for a medical officer whose work would be "mainly concerned" with tuberculosis. The Council felt that the Ministry of Health should have advised Boards to accept and implement the recommendations of the Council published last year, the chief feature of which was the appointment in every region of a regional chest physician, who should have both administrative experience of a high order and clinical ability at specialist level.

Wills

Dr. Brian Arthur McCubbin, of Portsmouth, left £2,997; Captain Bernard Henry Mooring Aldridge, R.A.M.C., £2,092; Dr. George James Rutherford, of Worthing, late Government medical officer in Ceylon, Nigeria, and the Gold Coast, £1,913; and Dr. Maximilian Walter Geffen, of Hampstead, £1,457. Mr. Augustus William Churchill, vice-chairman of J. and A. Churchill, Ltd., medical publishers, left £93,183.

COMING EVENTS

National Society of Children's Nurseries

A conference, convened by the National Society of Children's Nurseries (Norfolk House, Norfolk Street, Strand, London, W.C.2) will be held in the Conference Hall, County Hall, Westminster Bridge, London, S.E., on Friday, May 21, from 10 a.m. to 4.30 p.m. The morning session will be devoted to "The Training and Examination of the Nursery Nurse"; Dr. William Moodie will speak on "the need for training in child care," and Dr. Elizabeth J. Findlay will discuss administrative problems in training the nursery nurse. The general subject for discussion at the afternoon session will be "The Well-being of the Child"; Dr. John D. Kershaw will speak on team-work in child health, Dr. Neil R. Beattie on the care of the whole child, and Miss Mary Darlow on the well-being of Colonial children. Admittance to the conference is free, by ticket obtainable from the secretary of the society at the above address.

Medical Photography

The Medical Group of the Royal Photographic Society will hold its first exhibition of medical photography at the Royal Society of Medicine, 1, Wimpole Street, London, W., from Monday, May 24 to Saturday, May 29.

West London Hospital Medical School

The first Simpson Smith Memorial Lecture will be delivered at the West London Hospital, Hammersmith Road, W., on Thursday, June 10, by Mr. Norman Tanner on "Haematemesis and Melaena: an Investigation of the Place of Surgery in its Treatment."

B.C.G. Congress

The Institut Pasteur will hold the first International B.C.G. Congress in Paris on June 19-23. Topics to be discussed include the experimental study of B.C.G. and its use in human and veterinary practice. Further information may be obtained from: Secrétariat Général du Congrès du B.C.G., Institut Pasteur, 25, Rue du Docteur Roux, Paris XVc.

American Public Health

The 76th annual meeting of the American Public Health Association will take place on Nov. 8-12 at Boston, Massachusetts. Information may be obtained from the Association's Executive Secretary, Dr. R. M. Atwater, 1790, Broadway, New York, 19.

SOCIETIES AND LECTURES

Tuesday

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—May 18, 5 p.m. "Erythema-squamous Eruptions," by Dr. H. J. Wallace.

Wednesday

GLASGOW UNIVERSITY: DEPARTMENT OF OPHTHALMOLOGY.—May 19, 8 p.m. "Wounds of the Cornea," by Dr. W. O. G. Taylor.
HARVILL SOCIETY OF LONDON.—At 26, Portland Place, London, W., May 19, 8.15 p.m. "Clinical Research in Medical Education," by Prof. W. M. Arnott.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Convalescent Measles Serum

Q.—What are the dangers of using convalescent measles serum in a child up to 3 years of age as regards (1) immediate reactions in the nature of serum sickness, (2) remote reactions such as anaphylaxis and rhesus immunization? How can such reactions be guarded against and treated should they occur? Would it not be advisable to give the parents of any child so treated a note to say what had been done so that it could be handed to any doctor who in later years might propose to give the patient any other serum treatment?

A.—Convalescent measles serum or the more concentrated globulin used for the prophylaxis or attenuation of measles in young children will not cause immediate or more remote reactions like anaphylaxis or serum sickness, because the serum is a homologous and not a foreign protein. The risk of inducing an antibody response in an Rh-negative child (about 15% of the population) will occur only if the whole blood of an Rh-positive person is used. As this last procedure is not common in practice and the risk is a small one there seems little point in "earmarking" any child who receives such treatment.

Desensitization to Sulphonamides

Q.—Is desensitization to sulphonamides of any value in practice? How long does it last? Does desensitization to one sulphonamide desensitize to other members of the group? What is the best method to use?

A.—Sensitization to one of the sulphonamides is often specific for that particular drug, and another sulphonamide may be given with impunity. If this is not so, nothing can be done: there is no method of desensitization. If such drugs are withheld for about two years the sensitivity usually disappears spontaneously.

Fouchet's Test

Q.—What is the technique of Fouchet's test as employed in infective hepatitis and allied conditions? Is this test of value?

A.—Fouchet's reagent, which is used to detect bilirubin in urine and serum, is.

10% aqueous ferric chloride	10 ml.
Trichloroacetic acid	25 c.
Distilled water	100 ml.

For serum, place 1 to 3 drops of serum on a porcelain tile or dish, add an equal volume of reagent, and observe for twenty minutes. If the bilirubin concentration exceeds 2 mg. per 100 ml., a green or blue colour appears, the speed with which the colour develops indicating the concentration of the bilirubin. A few sera give a colour with little more than 1 mg. per 100 ml.

For urine, to about 10 ml. add 5 ml. of 10% aqueous barium chloride, mix and filter. A heavy precipitate should form; if it does not, add a few drops of ammonium or sodium sulphate solution. When all the liquid has passed through, unfold the filter paper and spread it on a piece of blotting paper. Allow one drop of reagent to fall on the precipitate, and observe for about fifteen minutes. A green or blue colour develops if bile pigment is present.

The writer uses the test as a routine method for urine, as it is the most sensitive of all practicable methods. For serum, it is less sensitive than the van den Bergh test and is not quantitative; its value is that it can be used to confirm a diagnosis of jaundice when no laboratory facilities are available. If it is positive in serum and negative in urine the possibility of a haemolytic jaundice should be considered.

Thursday

BRITISH INSTITUTE OF RADIOLOGY.—At Reid-Knox Hall, 32, Welbeck Street, London, W., May 20, 8.30 p.m., "The Abdominal Emergencies and Use of the Direct Radiograph," by Mr. J. N. Young and Dr. J. E. Bannen.
EDINBURGH ROYAL INFIRMARY.—May 20, 4.30 p.m. Honyman Gillespie Lecture: "The Genesis of Chronic Peptic Ulcer," by Prof. Ian Aird.
UNIVERSITY COLLEGE LONDON: DEPARTMENT OF PHARMACOLOGY.—At Physiology Theatre, Gower Street, London, W.C., May 20, 5.15 p.m., "Enzymes and Drug Action," by Mr. J. F. Danielli, Ph.D., D.Sc.

Friday

BRITISH INSTITUTE OF RADIOLOGY.—At Reid-Knox Hall, 32, Welbeck Street, London, W., May 21, 5 p.m. Meeting of medical members: 8 p.m., "Trends in Therapy Equipment Design," by Mr. A. J. Minns and Mr. D. H. Donaldson, M.Sc.
FACULTY OF RADIOLOGISTS.—At Royal College of Surgeons, Lincoln's Inn Fields, London, W.C., May 21, 2.15 p.m. Skinner Lecture: "The Natural History of Malignant Disease," by Sir Stanford Cade, F.R.C.S.
ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS. 58, Queen Anne Street, London, W.—May 21, 5 p.m. William Meredith Fletcher Shaw Memorial Lecture: "Contracted Pelvis," by Prof. J. M. Munro Kerr.
WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—At South Kensington Hotel, 41, Queen's Gate Terrace, London, S.W., May 21, 7.30 for 7.45 p.m. Dinner meeting. Some colour films of plastic surgery from Prof. Kilner's Clinic.

Saturday

NUTRITION SOCIETY.—At London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C., May 22, 10.30 a.m. Open scientific meeting and annual general meeting.

APPOINTMENTS

Robert George Hogarth, C.B.E., F.R.C.S., has been appointed Deputy Lieutenant for the County of Nottingham.
Leslie George Housden, M.D., has been appointed part-time to the Ministry of Health to advise on the development of schemes for teaching parentcraft.
Dr. Housden qualified in 1923 and proceeded M.D. (Lond.) ten years later. He was awarded the Sir Charles Hastings Clinical Prize in 1932. He has studied and written on mothercraft and child welfare.

BAAR, H. S., M.D., Ph.D., Pathologist, Children's Hospital, Ladywood Road, Birmingham.
HECTOR-JONES, DAVID, M.P.C.S., L.R.C.P., D.M.R.D., Honorary Assistant Radiologist, Hampstead General and North-West London Hospital, Haverstock Hill, N.W.
JETERISS, D., B.M., B.Ch., M.R.C.O.G., Assistant Surgeon to Obstetric and Gynaecological Department, Royal Devon and Exeter Hospital, Exeter.
WADE, PHYLLIS, M.B., B.S., D.M.R., Radiotherapist-in-charge, Royal Free Hospital, Gray's Inn Road, London, W.C.1.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Alexander.—On April 29, 1948, to Nancy (née Walmley), wife of Dr. F. G. Alexander, Birmingham General Dispensary, Small Heath, a sister for David.
Batty.—On May 5, 1948, to Rourdhill Nursing Home, Leicester, to Joan, wife of Dr. A. M. Feren, Bury, a son.
Ferguson.—On March 31, 1948, at Douglas, to Frances (née Wright), wife of Dr. A. M. Ferguson, a son—Robert Garrett Allen.
Henderson.—On April 10, 1948, at Edinburgh, to Dr. and Mrs. Ian R. Henderson, 10, Milton Drive, a daughter.
Hovenden.—On April 24, 1948, to Mary (née Powell), their second child, a daughter, at Carmarthen, Barrow, S.W.
Hovenden.—On April 24, 1948, at 43, Newlands Avenue, Radlett, Herts., to Daphne, daughter—Kate.
Mintley.—On May 6, 1948, at 43, Newlands Avenue, Radlett, Herts., to Daphne, daughter—Jennifer Jane.
Mintley.—On May 6, 1948, at 43, Newlands Avenue, Radlett, Herts., to Daphne, daughter—Jennifer Jane.
Young.—On April 28, 1948, at the Gables Nursing Home, Aylesbury, to Joyce (née Kellow), wife of A. R. C. Young, M.R.C.S., L.R.C.P., a son.
Leader, R.A.F., a son.

MARRIAGE

Key.—Winfield.—On May 4, 1948, H. A. Kent, Captain, R.A.M.C., and Mrs. Kay Winfield, widow of Flying Officer K. B. Winfield.

DEATHS

Beaumont.—On April 23, 1948, at Brandon, Suffolk, Edward Vincent Beaumont, M.B., B.S.
Burgess.—On May 6, 1948, at Edinburgh, Professor Arthur Henry Burgess, M.Sc., F.R.C.S., LL.D., of Ashlea, Cheshire, aged 74.
Chapman.—On May 7, 1948, at Moore Park, Cardross, Katharine Mary Chapman, L.R.C.P., S.E., L.R.F.P.S.Glas.
Dawson.—On May 2, 1948, at Carmarthen, Gwynon Davies, M.C., M.R.C.S., L.R.C.P.
Gray.—On May 6, 1948, at Edinburgh, John Alexander Gray, M.B., Ch.B., M.D., aged 71.
Hayle.—On May 4, 1948, at 25, Liverpool Road, Chester, Geoffrey Hahnemann, M.D., aged 71.
Raison.—On May 8, 1948, at Queen Elizabeth Hospital, Cyril Alban Raison, M.B., F.R.C.S., of 58, Harborne Road, Edgbaston, Birmingham, aged 56.
Scoones.—On May 5, 1948, at Rosedale, Hythe, Kent, Harold Edward Scoones, M.R.C.S., L.R.C.P.

Hay-fever due to Ragweed Pollen

Q.—An American suffering from a severe form of hay-fever due to ragweed pollen intends to visit Europe (British Isles, France, Switzerland) this summer. He asks whether ragweed pollen is present in these countries, and, if so, which are its months of flowering?

A.—The ragweeds (*Ambrosia* spp.) are native to North America and exist in Europe only as introductions. Five species have been noted at various times and places in Great Britain as native or adventitious plants, usually in the neighbourhood of ports. One—namely, Short Ragweed (*A. artemisiifolia*)—is known to have been established at one time at St. Anne's, Lancashire. The same species is reported as having occurred in France, mainly near certain ports, and also at a number of distinct localities in Switzerland. Ragweed pollen is easy to recognize, but only one grain has ever been seen on the thousands of slides the writer has exposed in various places in Great Britain since 1941. Unless an American visitor happened by mischance to walk into a colony of ragweed such as may perhaps exist here and there it is extremely unlikely that he would be exposed to this type of pollen in Europe. The months of flowering in Europe, as in U.S.A., are August, September, and October.

Diluent for Dimethyl Phthalate

Q.—What simple and easily obtainable solvents should be used for diluting dimethyl phthalate for application to the face and body?

A.—Dimethyl phthalate can be applied undiluted to the skin without harm. It is probably desirable, however, to use some diluent, especially for persons with sensitive skins. The amount of diluent should not be greater than 60% or the dimethyl phthalate will cease to be satisfactorily effective. Practical tests of certain diluents forming ointments and emulsions are described in a "Report on the Control of Midges," issued by the Department of Health for Scotland (H.M.S.O., 1946, 2d.), and reviewed in an annotation in the *Journal* of April 3 (p. 651). Several of the formulae recommended are now commercially available. One of the most satisfactory is as follows:

Lanette wax	5 g.	Oleic acid	..	27 ml.
Triphenylamine	9 ml.	Dimethyl phthalate	100 ml.	
		Water	100 ml.	

Treatment of Hirschsprung's Disease

Q.—What is the best treatment for Hirschsprung's disease in a young boy? Is sympathectomy still thought to give satisfactory results and, if so, what type of sympathectomy is indicated? Is treatment by spinal anaesthesia alone of any value?

A.—The pendulum of the treatment for Hirschsprung's disease is probably in process of swinging away from sympathectomy towards various forms of colectomy—in view of the generally satisfactory long-term results of the former. Sympathectomy is, however, still considered the treatment of choice in most centres. The two variations most favoured are: (a) bilateral division of the lumbar splanchnics (2-4 in number) and (b) lateral sympathectomy of the inferior mesenteric artery. The previously popular presacral neurectomy has been largely abandoned because of its side-effects in producing sterility and (possibly) because of its concomitant effect on the rectal musculature. Spinal anaesthesia alone has been reported by Telford and Scott (*British Medical Journal*, 1939, 2, 1224) as giving dramatic and lasting relief. No explanation of this phenomenon has ever been forthcoming.

Neuro-circulatory Asthenia

Q.—On the I.L.M. I have seen many cases of neuro-circulatory asthenia, especially in young married women. How can one best test to differentiate this condition from other conditions, and what is the most effective treatment?

A.—Neuro-circulatory asthenia, with its many synonyms, is a complex of mental, heart, and effort syndrome, is now generally regarded as a functional nervous disorder. The symptoms of this condition will be seen, on analysis, to be a mixture of the features of an anxiety state, the

hysteria" may be preferable. There is thus no distinction to be made between neuro-circulatory asthenia and anxiety neurosis; the first is an anxiety neurosis in which cardiovascular symptoms are more prominent than usual. Effective treatment is as difficult as for other anxiety states. The problem is well discussed by Paul Wood in his Goulstonian Lectures for 1942.

Retropubic Prostatectomy

Q.—My recent hospital statistics suggest that the public are beginning to appreciate that the modern operation of retropubic prostatectomy is reasonably safe. Such a realization will undoubtedly lead to an earlier seeking of advice by men in their early fifties—a goal towards which we have been aiming. Does this operation produce sterility and/or atrophy of the testes?

A.—It is doubtful whether the introduction of a new technique of prostatectomy will lead to a much earlier carrying out of the operation. Attention is drawn to the condition of enlargement only when symptoms of obstruction arise, and these are often delayed until the sixties and seventies. But even if retropubic prostatectomy were eventually to become the operation of choice, it would not materially affect the incidence of post-operative sterility. After enucleation the mechanism of ejaculation is usually destroyed, so that the semen seeps back into the bladder and is passed in the next specimen of urine. The patient is therefore generally sterile but cases of paternity after prostatectomy are by no means unknown. Atrophy of the testes should not be a sequel of the operation.

NOTES AND COMMENTS

Stability of Penicillin.—Mr. J. RAWLINGS ELLIOTT (Chief Pharmacist, Charing Cross Hospital) writes: In the reply concerning the stability of penicillin ("Any Questions?" April 17, p. 769) I would point out that some of the statements made are not in accord with usually accepted information. Lamellae and pastilles are supplied in a gelatin base which contains a certain amount of water, and therefore the penicillin in them is liable to undergo hydrolysis and become inactivated. Penicillin creams are actually thick emulsions containing water as the continuous phase, and the subject to the same decomposition; in fact the N(W)F monograph states clearly that the product must be labelled "Keep in a Cool Place" and "Use Within Seven Days." Lozenges, ointments, tablets, and oily suspensions, on the other hand, are prepared from ingredients free from moisture and may be stored at room temperature for several weeks, or in a refrigerator for a considerably longer period. It is important that the difference in keeping properties of the cream and ointment described in the *Pharmacopoeia* should be recognized if waste is to be avoided.

Exercise in Middle Age.—Dr. NOEL ALDER (Coleshill, near Birmingham) writes: Might I add to the exercises recommended for the middle aged and elderly ("Any Questions?" April 24, p. 816) one which is perhaps the most generally useful, entertaining, and least strenuous—namely, ice skating, especially figure skating? In contrast to walking exercises, which are often boring and even tiring unless taken on level ground, skating, in which friction is reduced to a minimum, requires a much smaller effort whilst training a much greater variety of muscles. In addition to those of the lower limb (extensors, flexors, rotators, ab- and adductors), a skater is constantly using his neck, shoulder, arm, back, and abdominal muscles—the mind being occupied with the fascination of learning or perfecting new figures. Measured rhythmical movements, poise, and balance, which can be acquired without great difficulty, will offer all the benefits of gentle exercise with the least amount of exertion. I can vouch for this from personal experience—I am in my 64th year—and from contact with others who still enjoy skating in the sixth and seventh decades of their lives.

Correction.—Since reporting "The Tragedy of Mount Scopus" (May 1, p. 869) we have learnt that Dr. Dostrovsky was not killed. Dr. Miszurski, the deputy administrator of the Cancer Department of the Hadassah Hospital, was among those killed.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY MAY 15 1948

THE ASSOCIATION AND PUBLIC HEALTH

A meeting of the Public Health Committee of the Association was held on April 30, with Dr. James Fenton in the chair. The Chairman of the Committee and the Executive Secretary of the Society of Medical Officers of Health gave a report of a meeting with the officers of the Ministry which they had attended in the position of county district medical officers in relation to schemes of decentralization. The question of compensation of suitable and acceptable alternative work without loss of status or salary was not provided for those displaced by such schemes had been discussed, together with superannuation and other matters. After hearing the report the Committee agreed to leave it to the Chairman and the Secretary to decide what amendments should be framed and submitted to the Ministry.

With regard to the Medical Practitioners (Fees) Regulations and the Association's claim for a revision of the fees for doctors called in by midwives, it was reported that fresh proposals were put forward by the Ministry differing in certain respects from the old Regulations, notably in the inclusion of a post-natal examination in the main fee. The Ministry's proposals did not fully meet the Association's claim, but certain improvements were made after more than one discussion, and agreement was eventually reached, subject to the reservation, recognized by the Ministry, that if after experience of the Regulations the fees were not found to be satisfactory in certain respects the matter should be looked into further.

The Committee had before it a list of fees recommended by the Association as payable by local authorities but not yet negotiated with local-authorities associations. It was pointed out that when the Spens Committee report appeared, which was expected in a few weeks' time, there would be a firmer basis on which to approach these associations, and it was agreed that the matter be taken up next session. Another matter which was postponed until negotiations began on the remuneration of specialists after publication of the Spens report concerned mileage allowances. While the mileage allowance was adequate for short journeys, it was less than adequate for long ones in view not of the cost of the car but of the absorption of the consultant's time. A consultation for a local authority entailing a total journey of 70 miles was mentioned, and it was pointed out that with domiciliary consultations long journeys might have to be undertaken with some frequency.

A recommendation made to local authorities in its area by the Lancashire and Cheshire Provincial Council on the consolidation of salaries and bonus of officers in their employment was mentioned. This recommendation imported a differentiation between male and female staff. In view of the Association's stand in respect of equal pay it was agreed that such differentiation could not be accepted, and that local authorities should be informed.

It was reported that the agreement on a modification of the interim revision of the salaries of medical officers in mental institutions had been ratified by the Council of the Association and by the Mental Hospitals Association and the bodies representing local authorities. The Chairman said that the increases for mental hospital officers were in line with the second interim Askwith recommendation. Dr. Buchan, in the name of the

Committee, thanked the Chairman, Dr. Fenton, for the great amount of work he had undertaken on this question of interim revision.

A letter from the County Councils Association was considered stating that, while in general the principle of local negotiation was not approved, the remuneration of public assistance district medical officers appeared to be a special case in which local negotiation was the best method of arriving at agreed salaries. The Chairman reminded the Committee that it was the decision of the Association originally that these salaries should be locally negotiated in view of the existing differences. It was agreed to intimate this decision to the Divisions and to ask the local-authorities associations to inform their constituents.

HEARD AT HEADQUARTERS

Maternity Benefit Regulations

The new Maternity Benefit Regulations have been discussed between representatives of the Insurance Acts Committee and the National Insurance Advisory Committee, whose chairman is Sir Will Spens. Under one clause of these regulations the Ministry has power to require a woman to submit to a medical examination in any case in which the correctness of the certificate is in question, and the deputation was anxious to know whether this meant that the medical practitioner's certificate could at any time be queried and a further examination ordered by an officer of the Ministry without reference to the woman's own doctor. They were told that the provision is designed to meet cases of abnormally delayed births in which circumstances suggest that a second medical opinion should be obtained. It will be the practice of the officer of the Ministry to consult the doctor or midwife informally when the confinement has not taken place by the date expected, and in the event of a second opinion the woman's doctor or midwife will be invited to be present. Another point made by the deputation was that the powers given to a midwife to determine a medical issue should be subject to more control than is provided in the draft regulations. Their fear was that similar powers might be extended to State registered nurses, and they urged that no reference for a second medical examination should be made without the knowledge of the patient's doctor, and that informal consultation between the medical referee and the midwife was undesirable. Sir Will Spens has undertaken to consider the submissions.

Interviewing Technique

There has recently been an amusing correspondence in an American medical journal on the opening remark to be used by a doctor in interviewing a patient. The crude, "What is the matter with you?" invites the reply, "That is what I came to you to find out," but it is possible to say, "What's the matter?" in a tone so solicitous that the patient responds automatically. The favourite question of one doctor from the Mayo Clinic is, "In what way have you been suffering that made you decide to seek medical counsel?" which would make many patients

test dazed at once. A warning is given against the omnibus question, "Tell me all about this pain: when it started; where you feel it; in what direction it extends." That should be broken up into small pieces. Sometimes it is necessary to get to know what a patient drinks, but it can hardly be approached with the words, "Are you a heavy drinker?" Better begin by asking how much he smokes, then his consumption of coffee, and so by a painless bridge to alcohol. As the general frankly says: "In building and getting a practice few will prove handier than a deft interviewing technique."

CERTIFICATES OF VACCINATION AND INOCULATION FOR PERSONS TRAVELLING OVERSEAS

There has recently been some confusion about the instruction issued by shipping companies and air lines to persons travelling to certain countries overseas that the certificates of vaccination or inoculation which they are required to produce on disembarkation must be countersigned by a medical officer of health. This requirement has been discussed with representatives of the Ministry of Health, and that department has now issued a circular to local authorities in England and Wales clarifying the position.

The difficulty has arisen because certain countries require evidence that the certificate of vaccination produced by a person disembarking at their ports of entry is genuine—that it has in fact been given by a registered medical practitioner in the country of issue. The World Health Organization is considering the position so that nations may agree on the matter, but in the meantime it is necessary to help travellers from the United Kingdom to meet the requirements of foreign powers and thus avoid the inconvenience of submitting them to a period of quarantine.

The evidence most readily accepted by authorities overseas is that given by a public health authority and identified by an official rubber stamp. The Ministry has therefore asked local authorities to arrange that anyone who requires to have a certificate of vaccination or inoculation authenticated for purposes of travel may have it stamped at the offices of the medical officer of health. It is suggested that for this purpose the stamp should bear the words "Signature of doctor authenticated" and the name of the local authority. The officer authorized to affix the stamp will be familiar with the signatures of the doctors practising in the area, or able to compare them with a list obtained for the purpose.

No responsibility rests upon the M.O.H. or his department to certify that the vaccination or inoculation has been properly carried out or, indeed, that it has been carried out at all, but solely to testify that the person signing the certificate is a registered medical practitioner. The responsibility for the accuracy of the certificate remains with the practitioner who issues it.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

- Metropolitan Borough Councils.**—Fulham, Hackney, Poplar.
- New-County Borough Councils.**—Dartford, Radcliffe (limited to future appointments), Tottenham, Walsend.
- Urban District Councils.**—Denton, Droylsden, Houghton-le-Spring, Hutton-with-Roby, Portlady, Redditch (restricted to future appointments), Tyldesley.
- Urban Sanitary Districts.**—Motherwell and Wishaw.

RETURN TO PRACTICE

The General Medical Council announces that the following have returned to practice: Mr. F. J. Radley-Smith, M.S., 10, St. Paul's Hospital, London, W.1; Mr. S. G. Chayton, M.B., 10, St. Paul's Hospital, London, W.1.

H.M. Forces Appointments

ROYAL NAVY

Surgeon Lieutenant J. Weir to be Surgeon Lieutenant-Commander.

ROYAL NAVAL VOLUNTEER RESERVE

Surgeon Commander F. E. Stabler, V.R.D., has been placed on the Retired List in the rank of Surgeon Commander.

Surgeon Lieutenant-Commander R. W. Smith has been placed on the Retired List.

Surgeon Lieutenant J. G. Craddock to be Surgeon Lieutenant-Commander.

Temporary Surgeon Lieutenant E. O. Davies, D.S.C., to be Surgeon Lieutenant.

Temporary Surgeon Lieutenant G. H. D. McNaught has been transferred to List II of the permanent R.N.V.R., in the rank of Surgeon Lieutenant.

Temporary Acting Surgeon Lieutenants R. T. W. McCall, P. H. Thorneycroft-Hall, and D. E. T. Laird to be Temporary Surgeon Lieutenants.

ARMY

Colonel J. R. N. Warburton, M.C., late R.A.M.C., has retired on retired pay and has been granted the honorary rank of Major General.

Colonel T. L. Dun, D.S.O., M.C., late R.A.M.C., having completed four years in the rank is retained on the Active List (superannuated).

ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonels J. Higgins and W. I. F. Powell have retired on retired pay and have been granted the honorary rank of Colonel.

Lieutenant-Colonels J. A. C. Kidd and F. Holmes, O.B.E., having attained the age for retirement, are retained on the Active List (superannuated).

Major J. A. V. Nicoll has retired receiving a gratuity and has been granted the honorary rank of Lieutenant-Colonel.

The surname of Lieutenant-Colonel R. G. Martyn is as now ascribed and not as stated in a *Supplement* to the *London Gazette* dated March 30, and *Supplement* to the *Journal* dated April (p. 102).

Captains (War Substantive Majors) A. D. Young, D.S.O., and T. E. Field, M.B.E., to be Majors.

Captains D. H. R. Montgomery, M.C., H. W. Peek, and Montgomery to be Majors.

Short Service Commissions.—Captain J. H. Gibson has retired and has been granted the honorary rank of Major. Captain F. C. Sayer, M.B.E., has retired on retired pay. Lieutenants W. Brodie, H. Binnie, J. Carswell, D. A. Chadwick, J. W. Clark, T. Dungav, K. D. Foggitt, G. H. Field, J. D. Llewellyn-Jones, J. MacLear, F. R. D. Minett, and J. M. Hughes to be Captains.

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

Major S. W. Barber has been granted the acting rank of Lieutenant-Colonel.

Captain (War Substantive Major) R. P. Kemp to be Major, and has been granted the acting rank of Lieutenant-Colonel.

Captains (War Substantive Majors) M. W. Gonin, D.S.O., T.I. and J. P. Parkinson to be Majors.

Captain (Acting Major) V. K. Drennan to be Major.

Captain W. E. Tucker, M.B.E., to be Major, and has been granted the acting rank of Lieutenant-Colonel.

Captains A. F. Alsop, H. J. Bell, M.B.E., R. W. Evans, and M. I. Braybrooke to be Majors.

Captain H. J. Gilbert has been granted the acting rank of Major. Lieutenant (War Substantive Major) D. MacD. Lyon, O.B.E., from Emergency Commission, to be Captain, and has been granted the acting rank of Major.

Lieutenant (War Substantive Major) G. E. W. Wolstenholme, O.B.E., from Emergency Commission, to be Captain.

Lieutenant (War Substantive Captain) J. C. Tainsh, from Emergency Commission, to be Captain, and has been granted the acting rank of Major.

Lieutenants (War Substantive Captains) T. C. MacInnes, B., Robinson, D. S. Dick, H. W. W. Good, J. F. Bereen, J. D. Henderson, and R. H. Ramsay, from Emergency Commissions, to be Captains.

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

War Substantive Major A. J. Warren has relinquished his commission and has been granted the honorary rank of Lieutenant-Colonel.

War Substantive Captains E. A. Kahn and D. C. Ross have relinquished their commissions and have been granted the honorary rank of Major.

War Substantive Captains R. M. Wiltshire, W. J. E. Darling, R. W. Jash, and S. W. R. Hutton have relinquished their commissions and have been granted the honorary rank of Captain.

Short Service Commissioners, Specialists.—War Substantive Major G. J. Dixon has relinquished his commission and has been granted the honorary rank of Lieutenant-Colonel; War Substantive Captain M. J. Bennett-Jones has relinquished his commission and has been granted the honorary rank of Major; War Substantive Captain F. G. W. Marson has relinquished his commission and has been granted the honorary rank of Captain. War Substantive Captain J. Y. D. Wakeham has relinquished his commission on account of disability and has been granted the honorary rank of Captain.

Lieutenants T. Hart, R. M. Duncan, K. D. Woolas, W. D. G. Tellam, S. S. Lawson, B. S. Cooper, P. W. Darby, A. Deuchars, R. B. Forbes, A. Goldberg, W. Garrett, E. G. Green, A. W. I. Hall, P. Holliday, M. M. Herbert, R. Houston, J. J. Hopkinson, K. Hughes, Jones, R. M. Inglis, D. H. Johnson, G. Jarratt, P. D. Kelsall, E. MacDonald, J. K. McMyn, F. McKerracher, R. R. W. Mirrey, J. R. Milne, A. McClelland, N. A. Oppenheim, D. A. Richmond, M. D. M. Reilly, J. A. Stoll, A. H. Swinbank, J. S. Scott, M. Symons, J. S. Swallow, J. H. M. Thomas, R. W. E. Watts, B. A. Woodger, J. T. Wright, D. Yuille, O. E. Owen, C. G. Teverson, H. A. Scott, M. P. Durham, and T. Wilson to be Captains.

To be Lieutenants: A. P. C. Bacon, C. W. Bird, J. H. Brenner, G. H. H. P. Croasdale, G. C. Davies, P. H. Foster, G. R. Freedman, D. Gall, H. H. Hayes, G. J. S. Herdman, P. W. S. R. Kennedy, R. H. A. MacGrath, H. L. T. G. Heron, R. R. Kennedy, R. H. A. MacGrath, H. L. Matthews, H. J. Moss, C. W. A. Murray, M. Skoblo, D. Walker, and J. B. Walker.

WOMEN'S FORCES

EMPLOYED WITH THE R.A.M.C.

War Substantive Captain E. K. Wacher has relinquished her commission and has been granted the honorary rank of Captain. Lieutenants E. M. Hargreaves, S. M. Dineen, and A. Faulkner to be Captains.

To be Lieutenants: Major J. G. Allen and Marie Killingworth

ROYAL AIR FORCE

B. Cohen to be Squadron-Leader (Temporary).
W. G. Thomson to be Flight-Lieutenant (Temporary).
To be Flight-Lieutenant (Temporary): A. G. Barnett, R. F. Jennison, D. V. Thomas, and W. Waugh.
To be Flying Officers (Temporary): A. Ashcroft, D. G. Boyle, W. R. Brown, R. E. Snow, S. Goldin, J. B. Lyster, R. M. H. McMinn, R. C. O. Saunders, I. McN. Walter, A. J. White, D. G. V. Whittingham, H. D. Young, and R. E. V. B. Young.

ROYAL AIR FORCE VOLUNTEER RESERVE

Squadron-Leader D. C. Devitt has resigned his commission, retaining his rank.

WOMEN'S FORCES

EMPLOYED WITH THE MEDICAL BRANCH OF THE R.A.F.

Flight-Lieutenant J. M. MacKay has resigned her commission, retaining the rank of Squadron-Leader.

INDIAN MEDICAL SERVICE

Colonel J. R. Kochhar has retired.
Lieutenant-Colonel D. P. Bhargava, O.B.E., has retired.

SPECIAL LIST (EX-INDIAN ARMY) BRITISH ARMY

Colonel N. Briggs, C.I.E., has retired.
Lieutenant-Colonel G. M. Moffatt, O.B.E., has retired and has been granted the honorary rank of Brigadier.
Lieutenant-Colonel D. Tennant has retired and has been granted the honorary rank of Colonel.

Majors (War Substantive Lieutenant-Colonels) W. M. Wilson and E. Parry have retired and have been granted the honorary rank of Colonel.

Majors W. S. Empey, O.B.E., P. A. Hubbard, A. M. Mackenzie, O.B.E., and W. C. Templeton have retired and have been granted the honorary rank of Lieutenant-Colonel.
Captains D. S. Wilson and A. S. Brown have retired and have been granted the honorary rank of Major.

COLONIAL MEDICAL SERVICE

The following appointments have been announced: G. W. R. MacGregor, L.R.C.S., L.R.F.P.S., and L. Goodman, F.R.C.S., Medical Officers, Gold Coast; C. S. Pitt, M.R.C.S., and A. R. Watson, M.B., Medical Officers, Kenya; J. J. Barton, M.B., Medical Officer (Temporary), Nigeria; R. M. Dowdeswell, M.B., Assistant Director of Laboratory Services, British Guiana; B. E. C. D.T.M.&H., Director of Medical Services, Uganda; J. M. A. Lowson, Hopwood, M.B., Medical Officer, Grade A, M.B., M.R.C.P., D.T.M.&H., Superscale Medical Officer, Grade A, Federation of Malaya; L. J. Charles, M.B., D.T.M.&H., Medical Officer of Health, Jamaica; G. C. Young, M.R.C.S., D.P.M., Specialist (Alienist), Uganda.

Association Notices

B.M.A. ANNUAL MEETING

CAMBRIDGE, JUNE 25 to JULY 2, 1948

When completed, the following form should be sent to the Executive Officer, Local B.M.A. Office, Guildhall, Cambridge

Form of Application for Accommodation

NAME (Block Letters).....

ADDRESS (Block Letters).....

I hereby authorize you to book on my behalf the accommodation detailed below and I undertake to pay for it in advance. (The rates are: Colleges £1 2s. daily with full board: Town Lodgings 9s. daily, Bed and Breakfast.)

...Single Room(s) (male) from the night of

till the morning of

...Single Room(s) (female) from the night of

till the morning of.....

...Double Room(s) from the night of.....

till the morning of.....

I would prefer Room in ".....College or in Town Lodgings"

*State College preferred or Town Lodgings

Signed.....

Date.....

Please give the following additional particulars:

Are you a graduate of Cambridge?

If so, what College?.....

Do you intend to bring a car?

Which Scientific Sections do you propose to attend?.....

Please remember to bring Ration Books or Emergency Ration Cards, Towels, and Soap. When booking is completed an account will be sent to you

PROPOSED WEMBLEY DIVISION

Notice is hereby given by the Council to all concerned of a proposal to form a Wembley Division comprising the area of the Borough of Wembley.

The proposed new Division will form part of the Metropolitan Counties Branch. Any member affected by this proposal and objecting thereto is requested to write to the Secretary of the Association by June 12, 1948, stating the objection and the ground therefor.

CHARLES HILL,
Secretary.

Branch and Division Meetings to be Held

METROPOLITAN COUNTIES BRANCH.—At B.M.A. House, Tavistock Square, London, W.C., Tuesday, June 1, 2.30 p.m. Ninetieth Annual General Meeting. Agenda: Report of Branch Council for 1947-8; report of Branch representatives on Central Council, 1947-8; election of officers for 1948-9; address by incoming President.

STAFFORDSHIRE BRANCH.—At Town Hall Annex, Burton-on-Trent, Thursday, May 20, 6.30 p.m. Annual general meeting. Presidential address by Dr. H. Vernon-Jessop: A Brief Outline of the History of Medicine from the Babylonian Period to the Sixteenth Century A.D. 7.45 p.m., annual dinner.

Willis, R. A.: Pathology of Tumours. 1948.
Wofenden, R. C.: Health Services in England. 1947.

disease and even complete occlusion of a large coronary vessel may be quite painless. Some other factor must exist to account for the occurrence of pain in some cases and not in others.

Anginal Pain and Normal Heart

There have gradually accumulated many accounts of patients with typical anginal pain from disease of tissues in the neighbourhood of the heart and in whom the heart is normal. These include:

Acute Mediastinitis or Mediastinal Abscess.—This results in severe pain substernally and between the shoulder-blades, and it may also pass down the arms and into the neck. Allbutt described a case of tuberculous mediastino-pericarditis with such symptoms.

Mediastinal Tumours.—These may cause pain substernally, between the shoulder-blades, and passing into the arms. It may be constant, intermittent, or paroxysmal (French, 1924).

Pneumo-mediastinum.—The presence of air in the mediastinum may cause temporary and often paroxysmal excruciating substernal pain passing into the arms, neck, jaws, and teeth (Scott, 1937).

Para-oesophageal Hernia of Stomach into the Mediastinum.—Roesler (1939) states that this may cause typical angina. An example of this is the following case.

Case 1.—A woman aged 57 attended the Royal Cancer Hospital under the care of Dr. P. E. T. Hancock on Nov. 18, 1947. Two years previously and a few days she had developed epigastric and substernal pain passing to the inter-scapular region and into both arms, especially the left. The pain came on about a quarter of an hour after meals, lasted about an hour, and was sometimes accompanied by vomiting. In addition she had periodic attacks of numbness and tingling in one or other digit of the left hand quite apart from the original attacks. The pain disappeared after two months but had returned a month before attendance. Its features were the same as during the previous attack. It was of considerable severity and made her afraid to eat. Three weeks previously she had vomited a small amount of "coffee-ground" material. Her appetite had disappeared and she had lost 7-8 lb. (3.17-3.62 kg.) in weight. On examination, apart from some slight tenderness on palpation in the middle of the epigastrium, no abnormal physical signs were to be made out. The blood pressure was 140/80 mm. Hg. No abnormal degree of peripheral arteriosclerosis was present and the cardiac apex beat was not displaced. The electrocardiogram was normal. A barium meal, however, showed the presence of a para-oesophageal hernia of the fundus of the stomach into the mediastinum to the left of the cardia. A fractional test meal revealed hypochlorhydria. The blood count showed: red cells, 4,040,000 per c.mm.; Hb, 62%; C.I., 0.77. She was treated under an ordinary peptic ulcer regime, including 10 minims (0.6 ml.) of tincture of belladonna half an hour before meals. Within two months her symptoms had completely disappeared and she had regained her former weight. A second barium meal showed no change in the radiological appearances.

Partial or Complete Oesophageal Rupture Within the Mediastinum.—Jackson and Jackson (1935-6) report that this causes typical angina. Mere distension of the oesophagus may have a similar effect.

A Dissecting Aneurysm of the Aorta in the Mediastinum.—While the dissection is taking place typical anginal pain may occur (Allbutt, 1915).

Spontaneous or Artificial Pneumothorax.—Anginal pain resulting from spontaneous pneumothorax has been described by Ontaneda *et al.* (1937) and from artificial pneumothorax by Lord (1925), Ballou and Francis (1929), Hamman (1934), and others. Obviously a unilateral pneumothorax may cause considerable displacement of the mediastinum when the latter is slack.

Pneumonia.—Anginal pain may occur during an attack of pneumonia (Kelman, 1919; Wassermann, 1920). In this illness the mediastinum may either be displaced or be the seat of glandular enlargement and inflammation.

Aneurysmal Dilatation of the Pulmonary Artery.—Anginal pain resulting from such a lesion has been described by Henschen (1905), Bedford (1929), and others. The disease may occur in comparatively young people, when it is often congenital in nature and unaccompanied by anoxia. The coronary vessels may then be completely normal and there is no question of involvement of their ostia by disease. The pulmonary artery lies within the mediastinum, and during its enlargement presses on the mediastinal tissues.

Aneurysmal Dilatation of the Aorta.—Angina is very commonly associated with such a lesion even in the absence of any evidence of aortic insufficiency. It is usually attributed to co-existing coronary disease or to involvement of the ostia of the coronary arteries by the aneurysm or a syphilitic process. The electrocardiogram may show no evidence of myocardial disease. The mediastinal structures are always disturbed, however. Mechanical distension of the aorta in dogs failed to give rise to anginal pain (Sutton and Lueh, 1930), though this developed when the periaortic tissues were damaged. It seems probable, therefore, that disease of the artery wall itself is not responsible for the anginal pain, but that pressure on periaortic structures is important.

Diaphragmatic Flutter.—This may give rise to paroxysmal anginal pain passing to the arms (Winkler 1933; Hofbauer, 1933; Porter, 1936). The electrocardiogram may be normal between the attacks but show an inverted T wave during them.

Pressure on the Diaphragm by Distension of the Stomach or Colon with Gas.—This may cause anginal pain localized to the left chest and arm (Lurje and Stern, 1931, and others). It may perhaps displace the mediastinum.

Disease of the Gall-Bladder.—This not uncommonly causes typical anginal pain, which may disappear when the gall-bladder is removed.

There is interference with the aeration of the blood in the lungs in many of the above conditions, as in cases of pneumonia or pneumothorax. A tuberculous mediastinal abscess is usually secondary to lung disease. A mediastinal tumour or an aneurysm may likewise cause collapse of a portion of the lung. Yet the complete lung on one side may be removed without causing angina. Moreover, in such conditions as pneumomediastinum, para-oesophageal hernia of the stomach, aneurysmal dilatation of the pulmonary artery, disease of the gall-bladder, or mediastinitis there is no suggestion of anoxia or of disturbance of the coronary arteries. In all the above conditions there is either disturbance of the mediastinal connective tissue by inflammation, pressure of one of the contained tubes or a gastric hernia, or displacement due to unilateral pressure of air in the pleural cavity, or there is disease of the diaphragm and the gall-bladder. Embryologically the connective tissue of the mediastinum, diaphragm, and gall-bladder all originate from the septum transversum. All such mechanical or inflammatory lesions cause a reflex arterial hyperaemia in the affected tissues. This means increased numbers of impulses in the appropriate vasodilator pain fibres in the posterior roots.

Other Causes of Anginal Pain

Apart from the above causes anginal pain may result from coronary sclerosis. It may also accompany hypertension (whether essential or renal in type or due to adrenal medullary or cortical tumours), aortic regurgitation or stenosis, mitral stenosis, and paroxysmal auricular fibrillation or tachycardia (see King, 1941; White, 1944). In such conditions the pain is usually brought on by physical exertion, flatulence, a heavy meal, or emotional upset. It may tend to occur during sleep. It is sometimes accompanied by flushing, and is occasionally followed by the appearance of herpes zoster in the segmental areas affected by the pain (see White, 1944). Anginal pain may also result from coronary thrombosis, acute cor pulmonale due to pulmonary infarction, cardiac trauma, the tearing of a papillary

myocardium (Todd, 1848; Glendy and White, 1936; Payne and Hardy, 1937), acute toxic myocarditis, hydatid infestation of the heart (Evans, 1832), metastatic tumours of the myocardium (King, 1941), abscess of the heart, and many other inflammatory states of the myocardium. Such pain may be the result from general disturbances, such as anoxia, anaemia, exposure to carbon monoxide, trichlorethylene ("trilene"), pentnucleotide, and nicotine, hyperinsulinism, Graves's disease, the injection of adrenaline, or anxiety states. It may constitute a tabetic crisis or occur as a withdrawal symptom in morphine or cocaine addicts.

The coronary vessels are surrounded by unmyelinated fibres, which accompany them to the various tissues of the heart. Some of these fibres must conduct vasodilator impulses. It is well known that the exposed heart is insensitive to painful stimuli. Sutton and Lueth (1930) showed that cutting, piercing, tearing, or pinching the myocardium or distension of the ventricle did not give rise to pain. On the other hand, tightening a ligature around the coronary vessels resulted in pain referred to a limb. Such a ligature included the unmyelinated fibres lying on the coronary vessels. Painting the vessel proximal to the ligature with 80% alcohol before this procedure prevented the onset of pain.

Gorham (1943) showed that tension on the coronary vessels may cause cardiac pain without producing any electrocardiographic signs of ischaemia. This suggests that the impulses giving rise to pain originate in the walls of the coronary arteries. By analogy with other blood vessels it would be expected that cardiac pain would result from excessive activity in coronary vasodilator fibres running in the posterior nerve roots. This is confirmed by the following observations.

1. Anginal pain is abolished by section or blocking of vasodilator pain fibres of D1-4 (5) on the corresponding side.

2. A lesion of any tissue of the body, including the heart, leads to local arterial vasodilatation, whether the lesion is due to infarction, trauma, or an infective agent. Exposure of an organ to anoxia, anaemia, or carbon monoxide has the same effect. This vasodilatation results from increased activity in the vasodilator pain fibres. When the agents affect somatic tissues pain results. When they cause dilatation of the pial and cerebral vessels a headache may appear. When they affect the heart they may cause angina. Thus infarction often leads to anginal pain and changes in the electrocardiogram. Trauma to the heart may likewise cause anginal pain and changes in the electrocardiogram similar to those of coronary thrombosis (King, 1941). Anoxia, anaemia, or carbon monoxide poisoning may have the same effects. Rupture of a papillary muscle which is followed by inflammation and vasodilatation leads to severe angina. Acute toxic myocarditis is accompanied by pronounced coronary vasodilatation and often substernal anginal pain. Bacterial and other infections and hydatid infestation involving the heart may also cause angina (King, 1941). In all these anginal states there occurs a transient or permanent coronary arterial vasodilatation. After infarction this is maximal in the first few hours, and it is at this time that the anginal pain is at its height.

3. A rise in blood pressure increases the work of the heart and so results in vasodilatation in the coronary vessels. It also produces a reflex vasodilatation throughout the body by way of the sympathetic nerves. This is shown by the high colour of the skin of many hypertensives. The vasodilatation in the pial and cerebral vessels causes headache. This generalized vasodilatation must augment the increased activity in the coronary vasodilator fibres caused by increased work. In such cases of hypertension angina is common.

4. In tabes there is destruction of the pain fibres in the posterior nerve roots. A tabetic crisis is painful and is accompanied by vasodilatation in the affected organ or tissue. It is usually followed by small haemorrhages. In some cases such as the following a form of an anginal attack.

5. During the withdrawal of drugs from morphine or cocaine addicts there is a general vasodilatation in all organs and angina pectoris frequently occurs.

6. An anginal attack often occurs in sleep when there is a general vasodilatation in the skin and other organs.

7. A heavy meal causes vasodilatation in the stomach and neighbouring tissues. It may induce an anginal attack in a subject of the disease.

8. An anginal attack may be accompanied by flushing of the face and upper part of the body—evidence of increased activity in vasodilator fibres.

9. Emotion often causes vasodilatation in tissues, and may induce an anginal attack in a subject of the disease or in one with a normal heart.

10. The injection of insulin not infrequently causes flushing of the skin and sweating (both signs of activity in cholinergic fibres), and one of its early effects is to produce increased gastric peristalsis, which is abolished by the application of atropine (Best and Taylor, 1943), and is thus due to activity in cholinergic nerve fibres. At the same time it often produces a migrainous or other type of headache. The hormone evidently stimulates cholinergie, including vasodilator, fibres. Not uncommonly it may induce an anginal attack, even in a person not normally subject to them.

11. In cases of Graves's disease there is increased activity of the heart, but also a notable vasodilatation in the tissues of the upper half of the body involving the mediastinum as well as the skin. Angina may occur on effort.

12. Nicotine likewise produces a general vasodilatation and not uncommonly headache. It is a well-known cause of anginal attacks.

13. Trichlorethylene, like other anaesthetics, causes general vasodilatation. It may induce angina, suggesting that the latter is due to excessive activity in vasodilator pain fibres.

14. In a case observed by me the intravenous injection of pentose nucleotide, a powerful vasodilator, into a patient with no sign of cardiac disease produced a typical attack of angina.

15. A coronary thrombosis with anginal pain may be followed by herpes zoster in the areas where the pain is felt. This indicates increased activity in vasodilator root fibres.

16. An attack of brachial radiculitis in a subject with no evidence of heart disease may cause angina of effort, which disappears when the radiculitis clears up. Such cases have been described by Nachlas (1934), Josey and Murphey (1938) and others. An example which I saw in the recent epidemic of brachial neuritis is here described.

Case 2.—An Army officer aged 26 was seen on Feb. 1, 1943. Three months before, while sleeping under canvas and exposed to damp, he developed severe aching and stiffness in the neck. His regimental medical officer diagnosed rheumatic torticollis. After heat and massage treatment the next month the aching spread to the shoulders and down both arms, especially the left. The pain was particularly severe at night and kept him awake. On rising there occurred stiffness, redness, and swelling of the hands and neck, crepitations in the shoulder-joints. The finger-tips tingled and felt numb. The arms felt weak and ached, especially after use. The symptoms persisted in spite of the heat and massage treatment. Three weeks before being seen he began to experience great distress on walking only 80 yards (metres) at an ordinary pace. This was accompanied by a constricted feeling round the upper thorax and a feeling of pressure under the upper sternum with pain, which passed down the inner side of both arms to the fourth and fifth fingers, especially on the left side. The pain was accompanied by a burning, tingling sensation in these fingers. The symptoms caused the patient to stop walking and would pass off within about half a minute, though the burning and tingling in the fingers persisted considerably longer.

Examination showed a marked tenderness on pressure of the cervical and brachial nerve roots, which felt thick. Pressure produced a tingling sensation in the fingers. The fingers were somewhat swollen, with thickening of the interphalangeal joints. The hands and forearms were reddened and

Power in the upper limbs was normal and there were no changes in the tendon reflexes. There was a marked hyperalgesia in the skin of the upper limbs and a distaste for handling of the limbs. No sensory loss could be made out. Crepitations were present on movement of both forearms and back of the hands produced an intensely disagreeable "triple response," which persisted for over an hour. In other parts of the body this procedure produced only a normal flare. A radiograph of the heart and cervical spine showed no abnormality, and an electrocardiogram was normal. The blood pressure was 120/80 mm. Hg and the pulse regular.

The patient was advised to rest in bed lying flat with the arms in slings, and acetyl-salicylic acid, 10 gr. (0.65 g.), was given three times a day. After a month the pains and the anginal symptoms had disappeared, though the hands were still swollen on waking in the morning. After a further month, using the limbs as little as possible, there was still slight swelling of the hands on waking. When seen a year later his symptoms had completely disappeared.

In this case there was no evidence of coronary disease, but the arm was painful and hot, and its tissues showed marked vasodilatation. The flare of the triple response was very easily obtained on the affected skin. This vasodilator nervous activity must involve deep tissues supplied by the affected roots and D 1-2 roots, supplying the coronary vessels.

Conclusion

In all cardiac conditions in which angina or coronary pain is experienced there is evidence of excessive activity in the vasodilator pain fibres passing to the coronary vessels, and this is evidently the origin of the anginal pain. Lesions of the derivatives of the septum transversum have also been shown to cause angina. Their nerve supply from the posterior nerve roots is established very early in development, and the nerve supply of the derivatives is therefore closely related if not identical. The mediastinal tissues are supplied with vasodilator fibres by way of D 1-5 posterior nerve roots, which also supply the heart. Lesions of these, as of other tissues, result in an increased activity in the vasodilator fibres passing in the same nerve roots as supply the coronary vessels. Hence any lesion of either mediastinum or heart which causes an increased activity in vasodilator pain fibres may result in angina. Such a conception brings angina into line with other painful vasodilatation in blood vessels. Thus angina is not directly due to anoxia or to vasoconstriction but to excessive attempts at vasodilatation.

The activity of any organ, including the heart, is accompanied by a reflex hyperaemia and by arterial vasodilatation, which occurs through the agency of vasodilator nervous impulses. The afferent nerve endings are stimulated by metabolites. Coronary sclerosis prevents vasodilatation during increased cardiac activity and allows the collection of metabolites. These cause excessive numbers of reflex impulses in the coronary vasodilator pain fibres in an attempt to produce further vasodilatation, and it is this excessive nervous activity which appears to give rise to the pain in such conditions.

Summary

Evidence is adduced to show that anginal pain may be caused by disease of both the tissues of the mediastinum and the heart. It seems to be due to excessive activity in the vasodilator pain fibres in the posterior nerve roots passing to the mediastinal structures and the coronary vessels, and it is not necessarily due to anoxia.

I would like to thank Dr. P. E. Thompson Hancock for permission to publish the details of Case 1.

TOLERANCE LIMITS TO RADIANT HEAT

BY

D. L. LLOYD-SMITH, M.D., B.Sc.(Oxon)

AND

K. MENDELSSOHN, M.A., D.Phil., F.Inst.P.

From the Nuffield Department of Clinical Medicine, Oxford

Radiant heat, a combination of visible and infra-red radiations, plays an important part in the practice of physiotherapy. In spite of this widespread use there have been few studies on the optimal and curative effects of measured amounts of radiant heat. The usual method of regulating the dosage of radiant heat is briefly to adjust the source used (incandescent filament bulb or resistance-wire heating element) at a distance from the patient's skin so that he feels comfortably warm but will be free from any hazard of burn. Since the conditions under which a burn will occur are poorly defined, it is necessary always to err on the side of safety.

It is perhaps not generally realized that heat is more easily administered by radiation than by convection and that accurate dosage can be prescribed (Evans and Mendelsohn, 1945a). A series of investigations carried out in this department and at the Clarendon Laboratory, Oxford, have led to the development of a suitable instrument for measuring radiation flux, including all visible and infra-red radiation (Evans and Mendelsohn, 1944, 1945b). The aim of the present investigation was to use this thermoradiometer for the determination of tolerance limits of the

Some of the beneficial effects of radiant heat are thought to be due to an analgesic action. It was hoped that this might be subject to direct experiment by comparing the sensitivity to series of pin-pricks of the area during exposure to radiant heat with that of a control area previously reported as equivalent in sensitivity. Of 39 subjects tested in this way, 29 reported that pin-prick felt duller over the exposure area. Of the remainder only one subject reported that pin-prick was sharper over the exposed area, while nine could detect no difference. Though this is a rather gross and approximate method of testing, it was believed to indicate that heat had a definite blunting effect on pain sensibility. This did not spread to areas with similar nerve supply, under these conditions at least, and thus would appear to be an effect on peripheral nerve endings.

FIG. 1.—Skin surface temperatures at tolerance limits for combined series (80 observations) arranged in 0.5° C. groups, and plotted as a distribution curve. The peak of the curve is seen to occur at about 44.5° C., and the scatter is small.

tions at least, and thus would appear to be an effect on peripheral nerve endings.

The measurements of tolerance limits, expressed in terms of the equilibrium skin temperature and radiation flux, showed a surprising uniformity. In fact our results indicate the presence of a well-defined general tolerance level in normal subjects. The observations have been presented as distribution curves, Fig. 1 showing skin temperatures ($^{\circ}$ C.) at tolerance limits, and Fig. 2 showing radiation flux in pyrrons. The main equilibrium skin temperature at tolerance

FIG. 2.—Data for radiation flux at tolerance limits for combined series (80 observations) arranged in 0.5 pyrron groups, and plotted as a distribution curve. The peak of the curve is seen to occur at about 2.4 pyrrons, and the scatter is small.

outline the lamp was raised and lowered several times before the final level of maximum radiation with comfort was decided, and each time the subject stated his tolerance to be at an almost identical level, although it was difficult or impossible for him to judge visually the distance of the lamp from the skin.

The difference in tolerance limits between the epigastrium and the interscapular area was small though statistically significant. The mean values of the observations on the epigastrium were 44.3° C. and 2.5 pyrrons compared with 44.9° C. and 2.6 pyrrons for the interscapular area (see Figs. 3 and 4). A difference of this small degree, when viewed in the light of clinical practice, would not necessitate separate dosage schedules for these areas. However, a significant difference does indicate that differences in skin structure or function, such as thickness, adiposity, pigmentation, richness of sweat glands and of nerve endings, may influence tolerance limits even though only in a small degree. The exact influence of these factors remains to be determined.

These findings are interesting when compared with previous reports. Carl Sonne (1929) studied the tolerance of five subjects to visible and short infra-red radiation for an exposure area of 3 cm. diameter on the inner side of the forearm, and found a value of 3.1 pyrrons. Laurets and Foster (1937), in a study of the tissue temperature gradient under radiant heat, found that most of their subjects could tolerate 1.8 pyrrons from an incandescent source, but they do not state that this was the maximum tolerable. Mayneord and Tulley (1943), using a different type of thermo-radiometer, in a series of 25 patients undergoing heat treatment found that there was a wide range of radiation intensities tolerable from 0.6 to 3.6 pyrrons, but most values were about 2 pyrrons. The skin temperatures were not reported. Elkins and Sheard (1941) found that, with a 250 -watt heat lamp, skin temperature of 41 – 43° C. over the foot and knee could be tolerated without discomfort, but the radiation intensities were not specified.

The present findings indicate that a fairly definite tolerance limit may be determined for normal subjects under standard conditions. With such a definite value as a guide, conclusions may be drawn regarding approximate dosage levels in clinical practice. Directions for treatment intensities as given in some textbooks of physiotherapy would probably produce incident radiation flux of less than 1 pyrron (Krusen, 1941; and Kovacs, 1945). A few measurements were carried out on patients undergoing clinical treatment, and the radiation flux varied from 0.75 to 1.5 pyrrons. Probably the present dosage of radiant heat is inadequate (Elkins, 1946) and could be increased with

FIG. 3.—Separate distribution curves plotted for skin temperatures at tolerance limits for epigastric (continuous line) and interscapular (broken line) areas under standardized conditions. A statistically significant though small variation occurs between these two distributions.

FIG. 4.—Separate distribution curves plotted for data of radiation flux at tolerance limits for epigastric (continuous line) and interscapular (broken line) areas. Again a statistically significant though small variation occurs between these two distributions.

Three adult female Africans each inadvertently received intravenously 10 gr. (650 mg.) of sodium bismuth tartrate aqueous solution. Two of the women collapsed and died with

two minutes, whilst the third collapsed after about six minutes and then appeared unconscious, cold, and with a barely perceptible and irregular radial pulse. No convulsions were observed in any of the patients. The survivor was given 1 ml. of nikethamide subcutaneously, and artificial respiration was applied. She recovered consciousness and was detained for observation.

Post-mortem examinations were performed upon the two fatal cases, but nothing of note was discovered except a remarkable and quite unusual degree of flaccidity of the heart, the musculature appearing otherwise normal. In both cases the lungs were extremely congested. At this time the true nature of the accident was not realized and the livers were sent to the Government analyst, who subsequently reported the presence of bismuth therein.

Because of this report, the survivor was treated with "amctor" and intravenous salines, but signs of bismuth poisoning rapidly appeared and a blue line was visible on the gums on the third day. Diminution of urinary output occurred almost at once, and complete anuria resulted on the fifth day. Intravenous sodium sulphate solution caused excretion to recommence and increase daily until 16 oz. (450 ml.) was passed on the tenth day, when death occurred. All urine passed after admission contained albumin, red blood corpuscles, and casts. The blood-urea estimations showed a rapid rise to a maximum of 240 mg. per 100 ml. on the seventh day, falling to 203 mg. on the day of death.

Post-mortem examination disclosed marked blue gingivitis. The abdomen contained about a litre of clear pale amber fluid. The liver was enlarged, soft, and covered with recent fibrinous adhesions which anchored it to the surrounding viscera. The kidneys were both very pale and swollen, with fine punctate haemorrhages on the surface. The lower colon and rectum were inflamed, with small haemorrhagic spots. No other finding of note was discovered. Microscopy of the kidneys revealed almost complete destruction of the tubular epithelium, with many granular and fatty casts. The liver showed little histological change, but both kidneys and liver contained quantities of extremely finely divided fat throughout the tissue.

The relative quantities of bismuth given and demonstrated by the analyst were as follows:

	Mg. Bismuth per kg. Body Weight	Mg. Bi per kg. Liver
Case 1 (immediate death)	13	40
Case 2 (.	10	30
Case 3 (delayed death)	11	23

I wish to record my thanks to the medical officers concerned for the courtesy of access to Case 3 and the clinical notes, to the Government analyst for the chemical estimations, and to the Director of Medical Services, Gold Coast Colony, for his permission to publish this report.

"The National Assistance Bill provides ample scope for the two classes of administrators—voluntary and governmental—to plan and work together," Mr. John Edwards, Parliamentary Secretary to the Ministry of Health, told the Lancashire County Citizens' Advice Bureau Conference at Manchester recently. He pointed out that after July 5 it would for the first time be possible to put up old folks' homes not to receive the destitute only but to house and provide care and attention to persons, whatever their financial resources, whose age, infirmity, or other circumstances required it. Under the Bill local authorities would also have to provide temporary accommodation for those in urgent need. "In these days of evictions, and with recent memories of flood, storms, and enemy action, I need not define this duty more precisely." The new Bill explicitly laid down that a local authority could contribute to the fund of any voluntary organization providing recreation or meals for old people.

A CASE OF MURINE TYPHUS IN LONDON

BY

T. B. DUNN, M.B., Ch.B.

In recent years there have been a small number of recorded cases of typhus fever in Britain, but all appear to have developed on board ship or within a few days of returning from an area of endemic typhus (Beach and Rennie, 1925; Agnew and Kyles, 1944). The following case is of interest as the patient had not been out of this country for over thirty years.

Case Report

The patient, a Russian-born Jew aged 61, was admitted to the Metropolitan Hospital under the care of Dr. Norman Hill on June 14, 1947, the ninth day of his illness. While at a cinema he had complained of sudden headache and was shivering. Next day he was confined to bed with fever, slight cough with scanty sputum, and severe headache, which remained the dominant symptom throughout his illness. He was treated at home with sulphadiazine, but the fever continued and he became delirious and prostrated. His breathing seemed to be "short" and difficult at times. On the seventh day a rash appeared being first noticed on the arms.

On admission the patient presented a picture highly suggestive of typhus fever despite the fact that careful examination showed no signs of louse or flea infestation, flea-bites, or excoriations. He was in low delirium, from which he could be roused, but could give no history and complained only of severe headache. He had a vivid and profuse maculo-papular rash on limbs and trunk, but not on the face, palms, or soles. The rash at first faded on pressure, though later it did not. The conjunctivae were suffused. He was dehydrated, had a dry skin and a dry tongue with thick blackish fur, and passed a small quantity of highly concentrated urine. The pulse was rapid and feeble. B.P. 90/70 P. 110. T. 101° F. (38.3° C.). There was passive congestion of the lungs, with a poor percussion note and fine crepitations at both bases. There was slight stiffness of the neck and back, but no other C.N.S. signs were found.

The cerebrospinal fluid contained 17 cells per c.mm., mostly lymphocytes, protein, 40 mg. per 100 ml.; chlorides, 700 mg. per 100 ml. A blood count showed 11,000 white cells per c.mm. (polymorphs 71%). The blood urea amounted to 50 mg. per 100 ml. on the tenth day. A radiograph of the chest confirmed the passive lung congestion. The Weil-Felix reaction on the eleventh day of the illness showed agglutination with *Proteus* OX 19 at a dilution of 1 in 125. Three days later the titre had risen to 1 in 500, thus confirming the diagnosis. No agglutination was obtained against OX 2, and against OX K the titre remained at 1 in 25.

On the twelfth day the temperature fell by crisis to 96° F. (35.6° C.), and remained at that level for three days before returning slowly to normal. He vomited many times on the day of the crisis and became incontinent of urine and faeces. For two days he remained very ill and collapsed, but thereafter his general condition improved steadily. His mental state improved slowly, but one week after the crisis his cerebration was still very slow.

He was later transferred to the Park Hospital, Hither Green, under the care of Dr. H. S. Banks, at whose request an investigation of the patient's serological reactions was made by Dr. Janet S. F. Niven at the National Institute for Medical Research. Using rickettsial suspensions as antigens, a positive reaction for murine (flea-borne) typhus was obtained, the antibody titre against the murine rickettsiae being 1 in 2,560, against louse-borne (epidemic) rickettsiae 1 in 640. Sera taken at later stages during and after convalescence showed a steady fall in agglutinating antibody with approximation of homologous and heterologous titres. The complete results of these and tests with similar South African sera will be published later by Drs. Gear and Niven.

The patient had left Western Russia 36 years ago. He did not admit to having had typhus fever or any febrile illness while

in Russia. He was employed as an egg-tester at the London docks, and two weeks before the onset of his illness had been despatched with a cargo of eggs arriving by ship from Poland—a journey which took seven days. He was quite definite that he had never had any louse infestation, but did admit to being bitten frequently by fleas while at work. The Ministry of Health intended to carry out a rickettsial survey of the rats in the docks, but could find no rats in that area.

Comment

The fact that the patient was a Russian-born Jew with no louse or flea infestation was suggestive of Brill's disease, which occurs sporadically along the North-east American seaboard amongst immigrants born in Eastern Europe. In these cases no louse or flea infestation could be found despite an illness characteristic of typhus fever. They were thought to be examples of murine typhus, but Zinsser (1934) after prolonged epidemiological and clinical studies considered them to be recrudescences of louse-borne typhus fever acquired at an earlier time of life in endemic typhus areas of Eastern Europe. Plotz (1943) showed by complement-fixation tests that these cases were serologically identical with louse-borne typhus. It is surprising that similar cases have not been recorded in this country despite a steady influx of Eastern Europeans since the first world war.

The present case, however, was subsequently shown by agglutination tests to be of the murine (flea-borne) type. This is normally enzootic in rats and can be transmitted to man by the flea vector. Brigham (1943) has brought forward evidence suggesting that mice may also act as carriers. If this does occur it must be uncommon, as other workers have on many occasions been unable to demonstrate mice infestation in areas of murine typhus where rats were infected. No examination of mice in the docks was made in this case.

As there was no rat infestation in that area of the docks, and as the disease is endemic in Poland, it seems reasonable to assume that the source of infection was the Polish ship. The egg-packing cases may possibly have been flea-contaminated either before loading or during transit. None of the patient's fellow workers were infected.

Although the man had a large number of contacts during the incubation period the risk of further human spread was small, as the typhus was of the murine type and flea infestation was apparently transient. No further cases were reported.

Most thanks are due to Dr. Norman H. Hill and Dr. H. S. Banks for their help and advice, and to Dr. Janet S. F. Niven for her help with the serological results.

TWO CASES OF TETANUS NEONATORUM

BY

C. A. St. HILL, M.B., Ch.B.

Department of Pathology, University of Liverpool

AND

H. LEDERER, M.D. Prague

Pathologist, Alder Hey Hospital, Liverpool

Tetanus neonatorum is a rare condition in this country and reports of its occurrence are hard to find. While occasional cases are recorded in foreign literature, the late reported in this country appear to be those of Johnston (1928) and Renton (1918). The occurrence, therefore, of two cases within two months prompted us to put them on record, together with an indication of the possible source of infection in one case.

Case Reports

Case 1.—The patient was a normally delivered male child born at home under the care of a district midwife. He was admitted on the eighth day with a 24-hours history of difficulty in feeding, apparently due to trismus. On examination he was seen to be extremely rigid, and the examination itself stimulated the onset of spasms of tetanic type. The umbilicus, from which the cord had separated before admission, showed a slight purulent discharge with surrounding inflammatory reaction. Aerobic culture of the pus produced a profuse growth of *Staphylococcus aureus*, but anaerobic culture revealed no *Clostridium tetani* at this stage. The case was diagnosed as tetanus neonatorum, and vigorous antitetanic treatment was started. The infant appeared to improve for two days, but collapsed and died on the third day after admission.

Post-mortem examination showed the picture of death from asphyxia. There was, in addition, evidence of mild inflammatory reaction around the umbilicus, while beneath the umbilical scar was a small bead of thick pus. The Gram stained films from the pus failed to reveal *Cl. tetani*, but anaerobic culture of the umbilicus and ligamentum teres produced a mixed growth of organisms from which virulent *Cl. tetani* was isolated.

Case 2.—This case occurred about seven weeks after that just described, and affected a male child 9 days old, also born at home. In this case labour had been difficult and there was first some suspicion that the symptoms were due to birth injury. However, after admission to hospital the clinical symptoms became typical. This child also died on the third day after admission in spite of vigorous treatment. Post-mortem examination revealed essentially the same picture as that seen in Case 1, but *Cl. tetani* was not isolated from the post-mortem material.

Investigation

The occurrence of these two cases, both delivered by different district midwives, led to investigations into the origin of infection. These were carried out by Dr. Ruth Bell, senior assistant medical officer of health in charge of maternity and child welfare, and Prof. D. T. Robinson, Liverpool City bacteriologist, to whom our thanks are due for the information given below.

The instruments, gauze, lint, ligatures, and dressings used by midwives were all cultured, but failed to reveal the presence of *Cl. tetani*. Both mothers, however, had sprinkled their infants' umbilical stumps with baby powder—of a different make in the two cases. These were obtained and cultured. The powder used on Case 2 gave a good growth of virulent *Cl. tetani*, but none of the organisms were isolated from the powder used on Case 1. Accordingly several samples of powder of the same brand as that used by the mother of Case 2 were obtained from various chemists in the city. In addition several other

Before Parliament exempts certain drugs from the provisions of the Pharmacy Act, 1933, the relevant provisions, which are set out in detail in Notice No. 78M, issued by the Commissioners of Customs and Excise, in relation to the exemption of the containers and contents of the containers, are those which consist of the following:—(a) any monograph in any form, (b) any monograph, or (c) any brands of baby powder were obtained to act as controls. All the samples of powder of the brand used in Case 2 showed the presence of numerous anaerobic organisms, though *Cl. tetani* was not isolated, while the control powders gave no such growth.

The makers of the suspect powder were approached and submitted the various raw materials used in its manufacture. These were: aluminium silicate (kaolin), magnesium silicate, boric acid, and perfume. The last three ingredients proved to be blameless, but from the kaolin an anaerobic spore-bearing bacillus was isolated, which, however, proved to be avirulent on animal inoculation. The use of this kaolin in the manufacture of the powder was discontinued by the manufacturers.

Summary

Two cases of tetanus neonatorum are described. Investigation of the origin of the infection suggests that the dusting powder used in one case may have been the cause. The origin of infection in the other case remains uncertain.

Our thanks are due to Prof. N. B. Capon for permission to publish the case histories; to Prof. W. M. Frazer for permission to use the results of the public health investigations; to Prof. A. W. Downie for carrying out virulence tests on the post-mortem material, and to Prof. Sheehan for advice in preparing these notes.

Medical Memoranda

Fat Indigestion in a Breast-fed Infant

This case seems worthy of record because the mother had a higher percentage of fat in her breast milk than I can find recorded, and because it demonstrates an uncommon cause of feeding difficulty in the breast-fed infant.

CASE HISTORY

The patient, a female infant aged 3 months, was brought to me with a complaint of vomiting, frequent large motions, and of crying after feeds. The birth weight was 8 lb. 8 oz. (3.85 kg.) and the weight at 3 months 12 lb. 13 oz. (5.81 kg.). The child was fully breast-fed with four-hourly feeds, and the history of vomiting and indigestion dated back to the end of the first month. At that time the vomiting was not troublesome, but it rapidly became quite severe; concurrently the motions became copious and more frequent than normal—up to five a day—but they remained normal in colour and consistency. Crying, with drawing up of the legs after feeds, became troublesome, especially in the latter part of the day, and in view of these findings the difficulty was thought to be due to overfeeding. The time at the breast was therefore cut down, boiled water being given before feeds to diminish the amount of milk sucked. These measures improved the vomiting considerably, the motions became more normal, and the rate of weight increase was diminished; this seemed to confirm the diagnosis of overfeeding.

At 2½ months, however, the vomiting became more severe again, the motions were frequent and green, and for the first time there was some weight loss. At 2½ months large friable curds began to appear in the vomits and in the motions, and a test feed at this time showed no evidence of overfeeding. The possibility of fat indigestion was considered, and this was confirmed by an analysis of a 24-hour specimen of breast milk, which showed a fat content of 7.4%. It was decided to wean the baby, as the mother had been losing weight steadily throughout lactation, and this was thought to be connected with her high fat loss through the milk. She made a point of saying that she took very little fat in her diet, and this corresponds with the finding of other workers that the diet has very little influence on the composition of breast milk.

The baby was weaned on to a modified National dried milk with a low fat percentage initially, and within a week the motions reverted to normal and the vomiting ceased, as did the crying after meals. The baby gained weight normally, and when she was last seen at the age of 8 months she weighed 18 lb. 9 oz. (8.42 kg.) and there had been no further difficulty with feeding.

A rather unusual feature of this case was that, in spite of a gross excess of fat in the breast milk, the indigestion was never severe enough to cause any significant loss of weight.

DISCUSSION

A survey of the composition of human breast milk in 21 cases of feeding difficulty in breast-fed infants was reported by R. C. Jewesbury (1937). He found a variation in the fat content of between 2.9% and 6.7%. The value of 7.4% in the case recorded above is unusually high, being 2.5% more fat than is present in Jersey cows' milk. The high fat value undoubtedly was the cause of the vomiting and curdy motions, as these cleared up completely after the infant was weaned. I would like to make it clear that weaning is not the usual practice in these cases, for they often respond to the giving of a protein preparation immediately before each feed and to being kept at the breast. In only a few cases is weaning necessary, and then as a temporary measure, the infant being fed on expressed breast milk from which the fat has been skimmed. Weaning in the above case was resorted to only because of the excessive loss of weight by the mother, which was thought to be due to the heavy loss of fat through the breast milk.

The method of obtaining the 24-hour specimen of milk is perhaps of importance, because the composition of breast milk is known to vary widely both with the time of day and even with the time during the feed at which the specimen is taken. This specimen was obtained in the following manner: at the 6-a.m., 2-p.m., and 10-p.m. feeds two teaspoonfuls were expressed from the first breast before the feed began and two teaspoonfuls from the second breast after the baby had finished sucking; at the 10-a.m. and 6-p.m. feeds one teaspoonful of the "middle milk" was expressed from each breast. Three specimens made up the 24-hour sample, and the fat content of the total amount was estimated.

Finally, it must be emphasized that "the milk disagreeing with the baby" is a very rare cause of difficulty over breast-feeding, and that cases thus labelled, and so often weaned as a result, are most commonly really due to overfeeding or underfeeding.

A Case of Multiple Embolism with Repeated Embolectomy

Below is recorded a case of repeated embolism in a patient with heart disease, in which embolectomy was performed twice within 14 days, with a successful result.

CASE REPORT

Mrs. J., aged 64, was admitted to St. Helier Hospital, Carshalton, at 12 noon on Nov. 23, 1946, having suddenly lost consciousness while on a trolley-bus with her daughter. At the time of admission she was completely unconscious, with stertorous breathing and generalized flaccidity. At 3 p.m. she regained consciousness and vomited some bilious material. It was then found that she had a past history of rheumatic fever in her teens, and had been taking digitalis at intervals over a long period. She had had occasional "dizzy spells," and at one time had been in bed for six months on account of heart disease.

On examination she was obviously an extremely sick woman, with dyspnoea, cyanosis, and marked oedema of the legs. The heart was enlarged, with signs of mitral and aortic disease. The pulse was irregular and the blood pressure 160/100. The liver was grossly enlarged, pulsating, and tender, and there were crepitations at the bases of both lungs. A diagnosis was made of advanced aortic and mitral disease with congestive failure and a small cerebral embolism.

At 5 p.m. on the same day the patient complained of coldness of the left hand. This was soon succeeded by pain in the whole limb, with definite duskeness of the skin. No arterial pulsation could be detected below the upper part of the left brachial artery, while the whole limb was blue, cold, and painful. The pulse at the right wrist was easily palpable. At this stage I was asked by the house-physician to see the patient. As she appeared to be desperately ill I waited for a couple of hours in the hope of spontaneous improvement in the left arm. After this time the local condition was no better, and an embolectomy was undertaken.

First Operation (Nov. 23).—Under local analgesia the brachial artery was exposed in its upper third. It was found to be pulsating in the whole length of the wound, and the embolus was not palpable. The adventitia was stripped from the artery, and a second incision

was then made in the lower part of the arm. The artery was found to be contracted and non-pulsatile, and the embolus was found under the upper corner of the incision. The artery was opened with a fine needle, which on removal was found to be $\frac{3}{4}$ in. (1.9 cm.) long. Blood was allowed to escape for a moment to wash the artery through. As the vessel was still in spasm suturing was by no means easy. The usual technique was employed.

Post-operative Course and Treatment.—She was given 200 mg. of dicoumarol and 10,000 units of heparin at once, followed by 5,000 units of heparin six-hourly for six doses. By this time the prothrombin index was 70% of normal and the prothrombin time was 45.4% above normal. Treatment for the heart condition was also employed. The patient was desperately ill for some days, and it seemed doubtful if she would survive. The pulse at the left wrist became faintly perceptible some fourteen hours after operation. She responded to treatment for her heart condition, and six days after operation her general condition was greatly improved and she had a strong pulse at the left wrist.

On Dec. 4 she had a sudden attack of dyspnoea with pain in the chest, which was attributed to a small pulmonary embolus; presumably thrombosis had also taken place in the right auricle. On Dec. 7 she had a sudden sharp pain in the right leg, which became cold and blue from the knee downwards. Pulsation was present in both femoral arteries and in the left dorsalis pedis artery. Vigorous pulsation could be felt in the right popliteal artery as far down as the middle of the knee-joint, where it ceased abruptly. A diagnosis of popliteal embolism was made.

Second Operation (Dec. 7).—Again under local analgesia the right popliteal artery was exposed and an embolus measuring $1\frac{1}{2}$ in. (3.75 cm.) in length was removed from the bifurcation of the artery. Dicoumarol and heparin were employed in similar dosage to that after the first operation. The leg rapidly recovered normal colour and warmth, and pain was relieved. Although the dorsalis pedis was not palpable, it was obvious in a few days that the circulation of the limb was satisfactory. The wound gaped after removal of stitches and had to be resutured on Jan. 21, 1947, under local analgesia. The heart condition improved gradually, and no further embolism had occurred when the patient was discharged on March 10, able to walk and take a moderate amount of exercise. Throughout the whole illness she had been an extremely plucky and co-operative patient.

Most surgeons now recognize the merit of early embolectomy in such cases, but there may still be many practitioners in this country who are inclined to adopt conservative measures, thus losing the six to ten vital hours within which a successful operation may be performed.

I am indebted to the physicians of the hospital, especially Drs. Bourd and Jelliffe, who undertook the medical treatment of the patient.

E. N. CALLUM, F.R.C.S. Ed.,
Late Surgeon, St. Helier County Hospital,
Carshalton, Surrey.

The "Kang Cancer" of North-West China

The "kang," or heated brick-bed, of Northern China has been described by many travellers, but the common and striking form of epithelioma associated with its habitual use has received little notice in the literature of malignant disease.

I spent the early part of 1947 at Lanchow, the chief city of Kuan Province in North-West China, and encountered "kang cancer" on five occasions; I was assured by many people that it is a common and widespread clinical entity throughout that area. The "kang," or oven-bed, is widely used by Chinese, Tibetan, and others to counteract the intense cold of winter in the high altitudes. It takes various forms, but is usually built of bricks or mud, and forms a hollow platform, 18 in. (45 cm.) deep in height, covered with loose wooden boards. Sometimes the bed has to be moved to make up the fire; sometimes an external grate in the outer wall of the house allows it to be heated up from outside. The fuel used may be coal, charcoal, or dung. The whole platform is covered with felts and quilts, and forms not only a communal bed but the place where the occupants of the house spend their leisure and eat their meals.

From personal experience—I have, when travelling, slept on such kang beds in Chinese and Tibetan households—I can understand the prevalence of such a bed, even though it is a source of discomfort and the acrid smoke escaping from the grate is a nuisance at times.

"Kang cancer" is a squamous-celled carcinoma arising in the skin over the great trochanter, and is probably in most cases a malignant degeneration occurring in a chronic burn scar. It may be compared with the much better known "kangri" epithelioma of Kashmir, which is caused by the constant irritation of a small portable brazier. Occasionally the "kang cancer" may arise over the os calcis or the olecranon, but I have not seen it in either of these sites.

Of the five cases that I saw one was an enormous ulcer of the thigh and buttock associated with malignant recurrence after late surgery, three were papillomatous tumours with broad bases and without ulceration, and the fifth was a small scirrhous ulcer with a nodular floor and raised irregular edges. The first four occurred in middle-aged men and were all in the right hip region. The fifth was in a very old woman and was on the left side. All except the first were treated by radical excision and skin-grafting.

A TYPICAL HISTORY

Mr. S. K. Wang, a Chinese opium-smoker aged 60, came from Lo Tu village (Tsinghai). He stated that he always slept on a kang, in which he burnt horse dung, and that he always slept on his right side. His only complaint was of a lesion over the right great trochanter which had been present for four years. He was quite healthy, apart from a large papillomatous tumour (see photograph) growing in the skin over, but not adherent to, the right great

FIG. 1

FIG. 2

Papillomatous epithelioma ("kang cancer") in a 60-year-old Chinese opium-smoker.

trochanter. The inguinal lymph glands were not abnormally palpable and were soft. Operation was carried out on May 28, 1947, under spinal analgesia, and consisted of wide excision of the tumour together with $1\frac{1}{2}$ in. (3.75 cm.) of skin all round and all tissues down to and including the deep fascia. Thiersch grafts were applied after three days, and the subsequent progress was uncomplicated.

COMMENT

The association with opium smoking is to be noted. A man is naturally more likely to burn himself unawares while under the influence of this drug, and it is presumed that the "kang cancer" is caused by chronic irritation (by friction and heat) of a burn cicatrix rather than by a carcinogenetic stimulant in the smoke. The development of epitheliomata in scars has been known since Marjolin's classical description in 1828. Two types of epithelioma occurring in scars—papillomatous and ulcerating—were described by von Brunn (1903), and correspond with the two types in my five Lanchow cases. The prognosis of such epitheliomata is relatively good. This, as pointed out by Iwamoto (1926), is because the underlying scar tissue discourages penetration by the neoplasm, which tends instead to spread out on the surface.

My acquaintance with this lesion was made during a quite brief visit to inland China. I am sure that anyone interested in the condition and permanently resident in this region could easily collect a large series of cases and study in much greater detail this locally abundant tumour, which is easily amenable to treatment and should be both preventable and easy to detect in its earliest stages.

Lectures on the Liver and its Diseases, comprising the Lowell Lectures delivered at Boston, Massachusetts, in March, 1947. H. P. Himsworth, M.D. (Pp. 204; illustrated. 18s. 6d.) Oxford: Blackwell Scientific Publications, 1947.

is one of the outstanding medical books of recent years. Everything that a monograph should be. It reveals the liver's intimate familiarity with the literature of hepatic disease not only of the present but also of the past century. It handles the material with the sureness of touch which can be attained only by personal work in the field. Much of it is original, and both the general outlines of the monograph and the detailed writing are models of clearness. To anyone interested in diseases of the liver it is indeed a fascinating

quarter of a century ago, as a result of the discovery of van den Bergh reaction, the pathology of the liver was seen largely in terms of the liver lobule and the biliary tract. Professor Himsworth emphasizes the circulation and the hepatic portal system, and his analysis is based on the vascular and its investing sheath of parenchymal cells. Swelling of liver cells, compression of the sinus, and ischaemia are the main factors in a large and apparently diverse group of diseases. After developing this vascular theme Professor Himsworth discusses the nutritional factors in hepatic disease. He makes a clear-cut distinction between massive hepatic necrosis, with its sequel of post-necrotic scarring, and diffuse liver fibrosis. The former results from deficiency of protein, more particularly of the amino-acid cystine; the latter from continued infiltration of the liver cells with fat and other poisons. He next considers the effects of micro-organisms and toxins on the liver and outlines the concepts of toxipathic and trophopathic hepatitis. He then discusses the syndromes of hepatic failure and makes a brief but vivid survey of the biology of the liver in man.

The virtue of this monograph lies in the elucidation and clarification of fundamental principles in the pathology of the liver, such as significance of the vascular pattern, the supply of blood and oxygen to the cells, and the effects of infiltration and swelling of the parenchyma. A criticism is that Professor Himsworth makes it all too simple. Circulatory factors may explain the distribution of massive necrosis of nutritional origin, but they hardly account for its explosive onset. Again, in reading Professor Himsworth's explanation of the protective action of thio-amino-acids in chloroform poisoning one just feels one has been the victim of a confidence trick, for his enthusiasm for his pet theory he has omitted any discussion of the part played by the sulphhydryl groups in the life of the cell and the nature of their combination with chloroform and arsphenamine.

Although we have learned a great deal about the pathology of disease of the liver, we are still ignorant of the mechanism of many of the symptoms. We do not know why patients with active hepatitis suffer from nausea and vomiting, why these symptoms may recur after the liver has apparently healed, and why they are aggravated by alcohol. We do not know why patients with chronic jaundice itch. The study of symptoms, in which the Mackenzie-Lewis school of clinical scientists excelled so much, has been much less informative than the experimental study of disease in animals. It has been a defect of clinical medicine and surgery in this country that its practitioners have not turned instinctively to the experimental laboratory for the solution of the problems which continually arise in clinical work. The crucial moment in Professor Himsworth's researches was when he decided that the best way of beginning studying T.N.T. poisoning in man was to feed T.N.T. to himself. He is to be congratulated that from this beginning he has been able to make such a notable contribution to our understanding of liver diseases in general, for in the crowded schedule of a professor of medicine of to-day these things are not done out of very special toil and enthusiasm.

L. J. WITTS.

CURRENT PSYCHOTHERAPY

Current Therapies of Personality Disorders. Edited by Bernard Glueck, M.D. Proceedings of the Thirty-fourth Annual Meeting of the American Psychopathological Association, held in New York City. (Pp. 296. 17s. 6d.) London: William Heinemann (Medical Books), 1946.

The American Psychopathological Association is to be congratulated on the wisdom of its Council in publishing this volume of papers read at its 1945 meeting. The contributions have been skilfully grouped into four sections: (I) The Modern Psychiatric Hospital; (II) The Physicochemical Techniques in Psychiatry; (III) Psychotherapeutic Techniques in Psychiatry; and (IV) Psychiatric Guidance and Rehabilitation Techniques.

The theme of the first section derives from the increasing appreciation of the social origins of the personality. The mental hospital must provide a culture which reflects that of our society in general and it must maintain many and varied relations with its community if patients are to be helped to return to society with confidence. The second section follows familiar lines and more interest will be aroused in the next section. Here are an account by Moore of his "bibliotherapy," a paper on the "Alcoholics Anonymous" movement, which is more successful as a description than as an interpretation of it, and an excellent paper by Slavson on group therapy. (In the latter, however, we note with surprise that the author has failed to appreciate the work of Bion and Rickman in this country, for he includes this under his term "mass therapy" rather than under "group therapy.") Also in this section is Lindner's evaluation of his hypno-analytic technique; unfortunately because of the author's "flashy" style it leaves an impression of uncertainty with the reader. The last section contains useful summaries of work in the adult and child fields, and there is an arresting final chapter on family guidance by L. K. Frank.

Dr. Glueck's broad vision of the tasks of psychiatry emerges in his presidential address: "The psychiatry of the future can become a significant and far-reaching prophylactic agent against the palpable confusions and perplexities of a world that is disintegrating before our very eyes." The picture of the therapeutic trends given by this volume certainly suggests that active groups of American psychiatrists are responding to this challenge by evolving theories and therapies in which the basic relationships of the individual with his social field are given full consideration.

J. D. SUTHERLAND.

OCCUPATIONAL SKIN DISEASE

Occupational Diseases of the Skin. By Louis Schwartz, M.D., Louis Tulipan, M.D., and Samuel M. Peck, B.S., M.D. Second edition, thoroughly revised. (Pp. 964; 146 illustrations and a coloured plate. 63s.) London: Henry Kimpton, 1947.

The second edition of this comprehensive textbook has additional illustrations and is a useful and full book of reference. It includes, in addition to doctrinal information on such topics as patch-testing and sensitization, carefully recorded facts from first-hand experience, together with a review of current opinion. The authors have enlarged the chapter on occupational diseases of the mouth to include occupational affections of the eye and a list of substances harmful to the eye. As might be expected, the chapter on the effects of irritant plants and woods is extensive, and the authors describe some sources of skin irritation happily unknown or uncommon in Great Britain. They discuss fully (mainly from the American point of view) the question of compensation, for information on which textbooks are so often consulted. However, the chapter on the medico-legal aspects of occupational dermatitis will appeal to readers in all countries and should strengthen the position of the doctor as an expert witness. Dermatitis from wearing apparel is dealt with fully, and many compensation cases may so arise.

The occupations described as giving rise to diseases of the skin are very wide, including those of meat porters and packers, dockers, veterinary surgeons, trappers, office workers, teachers, and salad preparers, to name only a few. The authors express the view that in most cases of mild industrial dermatitis immunity to the skin irritant will develop if work is continued with the protection of special ointments and clothing. This is of some interest, since it does not accord with the general trend of opinion in Britain. They dispose in three pages of the general

treatment of occupational diseases of the skin, and devote much space to considering the prevention of dermatitis in different industries, which leads to some repetition. One of the introductory chapters is, however, devoted to general methods of prevention under the headings of protective clothing, protective creams, and industrial skin cleansing. The investigation of occupational skin disease is described in detail, with emphasis on patch-testing to identify the causal agent or agents, but variations in the methods of work of individuals or groups is evidently of less significance than in Britain. Extensive bibliographies are given at the end of each chapter, and the index is comprehensive.

SIBYL HORNER.

ST. THOMAS'S HOSPITAL

The Story of St. Thomas's 1106-1947. By Charles Graves. (Pp. 72. 8s. 6d.) London: Faber and Faber.

The great teaching hospitals of London have on the whole been well served by historians. St. Thomas's in particular owes much to the devoted labour of the late Prof. F. G. Parsons, whose three-volume history (1932-6) is a model of its kind. Although admirably adapted to the needs of historians and antiquarians Parsons' book left room for a short popular account of the hospital designed for the general reader. The choice of so experienced an author as Mr. Charles Graves to write such a book was a happy one, and has resulted in the production of a worthy tribute to the spirit and tradition of an institution that has "survived the dissolution of the monasteries, the depredations of kings, fire, plague, and some of the worst bombing of the blitz." It was printed in Czechoslovakia, and special praise is due to the illustrations, which are well chosen and set a new standard of excellence.

In the first chapter the author tells how the Priory of St. Mary the Virgin was established in Southwark before the Norman Conquest and how it carried out its work of relieving the sick. The Infirmary, situated on the site now occupied by Southwark Cathedral, was known as St. Thomas's Spital from the time of Thomas à Becket's canonization in 1173. Mr. Graves sets the early history of the hospital against its social background and sketches in the state of contemporary medicine with great skill. The closure of the priory and hospital at the Dissolution of the Monasteries in 1540, its restoration as one of the three Royal Hospitals by Edward VI in 1553, and its fortunes during the Great Plague and the Fire of London are notable episodes in the story. Many interesting extracts are given from old hospital records and standing orders relating to methods of treatment, nurses, resurrectionists, and the exclusion of illicit beer from the wards. The beginnings of modern medicine and the growth of the teaching hospital are next described, with special reference to such great figures as Wharton, Mead, Cheselden, and Astley Cooper. There is a good account of that period of nearly a century when St. Thomas's and Guy's were united for teaching purposes, as well as of the more recent history of the medical school and the establishment of special clinics and services. Almost half the book is about Florence Nightingale and the development of modern nursing, but this section is very well done and is not disproportionately long in a book intended for the general reader. There is an inspiring account of St. Thomas's part in the war years. At this turning point in the history of British medicine it is well to be reminded of the achievements and traditions of a hospital that has given continuous service to the sick and poor of London for more than 800 years.

W. J. BISHOP.

The report of the Water Pollution Research Board for 1946 describes some of the activities of the Water Pollution Research Board at Welford, Hereford, and describes the work done on the treatment of effluents from polluted waters. Sea water is pumped into the estuary and treated with chlorine; the mussels are then collected and stored for about 16 to 20 hours, and during this time the mussels filter out a great deal of faeces and pseudo-faeces. After the mussels have been stored for 16 to 20 hours the water the mussels are free from faeces and pseudo-faeces. Research has also been conducted on the effect of the effluent on the growth of percolating filters at a sewage treatment works. The effluent is found to be free from pollution from engineering works. The report is published by the Water Pollution Research Board.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received.]

New and Nonofficial Remedies. 1947. Issued by the Council on Pharmacy and Chemistry of the American Medical Association. (Pp. 749. 21s.) London: J. B. Lippincott. 1947.

A list of preparations found acceptable by the American Council on Pharmacy and Chemistry up to Jan. 1, 1947.

The British Journal Photographic Almanac, 1948. (Pp. 16s.) London: Henry Greenwood. 1948.

Contains details and formulae of photographic methods.

Human Physiology. By F. R. Winton, M.D., D.Sc., and L. Bayliss, Ph.D. 3rd ed. (Pp. 592. 25s.) London: J. and A. Churchill. 1948.

A textbook intended primarily for medical students.

What Life Has Taught Me. By W. R. Inge and others. (Pp. 10s. 6d.) London: Odhams Press. 1948.

A collection of essays by 25 distinguished men and women.

Tuberculosis. By F. M. Pottenger, A.M., M.D., LL.D., F.A.C. (Pp. 597. 60s.) London: Henry Kimpton. 1948.

An account of the pathology, symptomatology, diagnosis, and treatment of pulmonary tuberculosis.

Practical Photomicrography. By R. F. E. Miller. (Pp. 101. 10s.) London: Percival Marshall and Co. 1948.

A practical manual for the beginner.

The Mothercraft Manual. By M. Liddiard, S.R.N. (Pp. 176. 5s.) London: J. and A. Churchill. 1948.

An outline of the principles taught by the late Sir Truby King.

A Text-Book of Midwifery. By R. W. Johnstone, C.B.E., M.D., F.R.C.S.Ed., M.R.C.P.Ed., F.R.C.O.G., F.R.S.Ed. (Pp. 570. 30s.) London: Adam and Charles Black. 1948.

The text has been revised and there is a new section on the Rh factor.

Hospital Care in the United States. (Pp. 631. \$4.50 at New York: The Commonwealth Fund. London: Geoffrey Cumberlege (Oxford University Press). 1947.

A study of the hospital services by the Commission on Hospital Care.

Inside the Asylum. By John Vincent. (Pp. 115. 6s.) London: George Allen and Unwin, Ltd. 1948.

An autobiography.

Principles of Management. By M. A. Cameron, M.A. (Pp. 2s. 6d.) London: George G. Harrap and Co. 1948.

A short discussion of management, administration, and leadership.

Die Röntgendiagnostik der Wirbelsäule. By Adolf L. 2nd ed. (Pp. 364. Paper covers, 56 Swiss francs; still 60 Swiss francs.) Vienna: Springer-Verlag. 1948.

A textbook of the radiological diagnosis of disorders of the vertebral column.

The British Encyclopaedia of Medical Practice. "Medical Progress" and "Cumulative Supplement," 1948. Edited by E. Horder and others. (Pp. 539. £2 7s. 6d.) London: Butterworths and Co. 1948.

Radon: Its Technique and Use. By W. A. Jennings, B.S. A.Inst.P., and S. Russ, C.B.E., D.Sc., F.Inst.P. (Pp. 222. 10s.) London: John Murray (for the Middlesex Hospital Press). 1947.

An account of the production of radon and its uses in medicine and industry.

A History of the Norfolk and Norwich Hospital. By A. Cleveland, O.B.E., M.D., F.R.C.P. (Pp. 179. 15s.) London: Jarrold and Sons. 1948.

The history covers the years from 1900 to 1946.

The Venereal Diseases. By J. Marshall, M.D., B.S. (Pp. 369. 21s.) London: Macmillan. 1948.

A practical manual for students and practitioners.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY MAY 22 1948

ORGANIZATION FOR SPECIALISTS

For many years the British Medical Association has tried to arouse the interest of consultants and specialists in medical organization and medical politics. It has not been easy to do this, because of the absence of any consultant service for the insured population. The B.M.A. through its Hospital Committee and through its Special Groups has done much to encourage consultants to tackle on a systematic basis problems common to them all. Now that consultants and specialists (or specialists for short) are to work in a National Health Service open to the whole community they are faced with a situation that has been familiar to insurance practitioners since 1912. Consultants and specialists need a peripheral and central organization if their interests are to be safeguarded in such matters as remuneration, terms and conditions of service, scope of work, and so on. The Council of the B.M.A. has considered this problem with much care and has described in a recent issue of the *Supplement*¹ its plan for representation of specialists' interests. This part of the Council's report is reprinted in this week's *Supplement*.

The Council proposes that there should be set up Regional Consultants and Specialists (including Hospitals) Committees, and a Central Consultants and Specialists Standing Committee. In doing this it is filling a gap left in the present Act. The Act provides for the formation of Local Medical Committees in the areas of the Local Executive Councils, but provides for no similar committees for specialists. The B.M.A. is therefore setting up Regional Consultants and Specialists Committees in the areas of Regional Hospital Boards. It considers that the majority of the members of each committee should be elected by the consultants and specialists in the region, and that there should be separate representation for those practising whole-time. It proposes, too, that not less than one-quarter of those elected to the Regional Committees by the staffs of non-teaching hospitals should be part-time consultants and specialists. On these committees, too, should be representatives of Local Medical Committees, of medical officers employed whole-time by local authorities, and of medical superintendents. For the first year it is suggested that elections should be on the principle of representation of hospital staffs or groups of hospital staffs. The Central Consultants and Specialists Committee will replace the B.M.A.'s present Consultants and Specialists and Hospital Committees. The majority of the members of the new Standing Committee will be elected by the Regional Consultants and Specialists Committees, and representation will be

given to the Special Groups and to practitioners engaged in part-time specialist practice; in addition there will be members elected by the B.M.A. Council and by the Insurance Acts, Public Health, General Practice, and Industrial Medicine Committees. The B.M.A. describes this as a functional machinery not forming part of the Association's constitution but linked closely with it at the centre and also at the periphery. As with the constitution of the Insurance Acts Committee, membership of the B.M.A. is not a requirement for membership of the Regional and Central Committees. This form of organization should satisfy the most thorough-going democrat, and is based upon the long and unrivalled experience of the B.M.A. in such matters.

Some consultants and specialists have already expressed surprise² at the suggestion made in the *Lancet* that there should be set up a new organization based largely upon the Royal Colleges and teaching hospitals. It is not easy to treat the suggestion seriously, and we may doubt whether the Royal Colleges would see fit to branch out into medical organization and medical politics when there is in existence a body fitted for this purpose to which more than 90% of the consultants and specialists of this country belong. The President of the College of Surgeons, we understand, has recently reminded the Fellows of the College that by its Charters it exists primarily and essentially to promote and encourage the study and practice of surgery. In his Charter to the Royal College of Physicians Henry VIII declared his intention to institute "a perpetual College of learned and grave men who shall publicly exercise medicine." For the Colleges to embark on the formation of a new organization as is suggested by the *Lancet* would, we believe, be against the spirit and intention of their Charters and be an act of duplication wasteful of time, money, and effort at a moment when there is a grave shortage of medical men for the new service which starts on July 5. The *Lancet* seems to suggest that the new organization will decide what salary grades individual consultants shall be placed in. Any such idea would be completely unacceptable to consultants and specialists and, we may believe, to those responsible for administering the Regional Hospital Boards. The specialist working in the National Health Service will be in contract with the Regional Hospital Board, which, within the framework of the Spens Committee recommendations, will determine the remuneration to be offered for different kinds of work.

To suggest, as our contemporary does, that there might arise a conflict between the interests of the general practitioners and consultants is indeed ill-considered: and to follow this with a proposal for a consultants' medico-political organization would seem to aim at creating antagonism between two important groups of one profession. The Royal Colleges, and especially the Royal College of Physicians, have great historical traditions as bodies of learned men concerned with the intellectual standards and life of medicine. Their function is defined in their Charters and exemplified in their activities. The function of the British Medical Association in medical politics and organization is as clearly defined. The B.M.A. has its

¹ *British Medical Journal Supplement*, 1948, 1, 77.² *British Medical Journal*, 1948, 1, 950.

and possible part to play in safeguarding the interests of the consultants and specialists as it has done for the past thirty odd years for the insurance practitioner. It has set up a fully representative functional machinery for consultants and specialists in the new service. We may hope that the proposals for a new and separate organization are stillborn and that the medical profession will maintain the power in negotiation that comes through unity.

CUTANEOUS CANCER

Cancer of the skin is more common in the white than in the coloured races. This may be because it usually arises on exposed parts, especially on the face, and the pigmentation and thickness of the skin determine the degree of protection against ultra-violet irradiation, which—in the region of 2,900 to 3,340 Å—is probably important in this connexion. Those with fair hair and sensitive skins that freckle but do not tan are more susceptible than the dark-skinned. In cattle there is evidence that epithelioma occurs much more commonly upon the white areas than upon the normal hide. In surveys conducted in the U.S.A. it has been shown that in the south cancer of the skin may constitute some 50% of all primary cancers, whereas in Chicago the corresponding figure may be little more than 10%. A further survey has shown that, while in certain parts of the continent cancer of the skin in the white population may form from 20% to 40% of all primary growths, in negroes inhabiting the same areas the incidence is no higher than 2% to 4%. Europeans settling in Australia are known to be some ten times more susceptible to carcinoma of the skin than Europeans in Europe. There is, of course, great individual variation. The extreme case is that of xeroderma pigmentosum, fortunately very rare, where the tendency to keratotic and carcinomatous changes in the skin of the exposed parts develops in early childhood and may become uncontrollable before adult life is reached.

In addition to exposure and light, other forms of radiation—heat, x-rays, and radium—as well as mechanical and chemical irritation may provoke cancer. Oil and tar products are dealt with at length by Henry¹ in his monograph on cancer of the scrotum. Hieger² and others have shown that powerfully carcinogenic hydrocarbons can be isolated from pitch and tar and can be synthesized. A high incidence of keratotic and carcinomatous growths of the skin after relatively short exposure in workers engaged in the manufacture of briquettes has been observed in recent years. Arpall Campbell³ showed that road dust containing 2% tar could produce in mice cancer of the skin and produce metastases.

Exposure of the skin may determine the development of carcinoma, though long-continued exposure and contact with the more potent sources. Both basal-celled and squamous carcinomas can arise in this way, but the latter are more common. Chronic disease causing chronic inflammation, such as pyoderma, and, other things being equal,

the earlier in life the disease appears, as with lupus vulgaris, the more likely is malignant change to supervene. A combination of irritant effects is more carcinogenic than a single agent, so trauma to a scar, x-ray therapy for lupus, and similar combinations should be avoided so far as possible. For the same reason, those who are recognizably prone to cancer should avoid obvious climatic or industrial hazards.

Cancer of the skin arises most frequently between the ages of 50 and 60 and is much more common in the male—this applies particularly to epithelioma. It must be emphasized, however, that the mortality from cancer of the skin is low (under 2%), and five-year cures are obtained in something like 97% of cases. Basal-celled carcinomata are regarded as locally malignant only, though Sachs⁴ has described metastatic lesions in three cases. Occasional areas of transitional or squamous and horny-celled growth are seen in serial sections of most basal-celled carcinomata and it is sometimes difficult to classify these lesions; but it remains a fact that all cancers of the skin, including epitheliomata, are relatively benign, do not readily give rise to involvement of glands, and even then are commonly cured if treated early. This is not true of cancers involving mucocutaneous junctions or mucous membranes—malignancy is greater and the prognosis is less favourable. The smaller the lesion the better the prognosis, and in all cases only about 10% develop more than one lesion.

Methods of treatment are various and are equally effective in the hands of the experienced. Surgical excision, destruction by diathermy or some other form of electrocoagulation, radiotherapy, or a combination of these measures, are all effective provided the lesion is completely destroyed at the first treatment. Not all carcinomata are radio-sensitive, but for those that are—the vast majority—gamma-ray therapy is probably best for large lesions or for those awkwardly situated. The cicatricial form of rodent ulcer, lesions involving bone or cartilage or glands, and recurrent lesions are best treated surgically. For small lesions, in which the diagnosis is uncertain and histological confirmation required, surgical excision is preferable to preliminary biopsy.

Epitheliomata sometimes grow rapidly to the size of a large pea or a cherry in the course of a few weeks. In appearance they may resemble an acute infective lesion, such as an infected sebaceous cyst or molluscum contagiosum. This early threat of grave malignancy is not usually maintained and the response to treatment is often good. Other epitheliomata progress so slowly that they may for years be mistaken for patches of chronic eczema or psoriasis. Such carcinomata are often intra-epidermal and may remain so for years without penetration or invasion of the dermis. Paget's eczema of the nipple, Bowen's disease, "erythroplasia" of Queyrat (generally affecting the glans penis), and the multiple benign epitheliomata of the trunk described by Graham Little are examples of this chronic form of the disease, which may, however, at any time assume a more malignant phase.

The study of skin cancer suggests some individual, familial, and racial predisposition, and reveals the great

¹ *Lancet*, 1933, 1, 233.

² *Arch. Derm. Syph., Chicago*, 1946, 53, 599.

³ *Brit. J.*, 1946, 53, 397.

importance of external irritants as a cause. Elliott and Welton³ suggest that a predisposition to cutaneous cancer was inherited in 37% of some 2,000 cases recently reviewed. The satisfactory response to treatment and the low mortality are encouraging, though no doubt largely due to ease of observation, early diagnosis, and accessibility. The almost complete absence of those hideous and destructive lesions seen so often twenty and thirty years ago is a testimony to our steady advance in knowledge and in methods of treatment, to earlier diagnosis, and to the more enlightened attitude of the public.

SMEGMA AS A CARCINOGEN

Two cancer research workers in the U.S.A., Plaut and Kohn-Speyer,⁴ have recently reported that horse smegma injected into or painted on the skin of mice produces a small percentage of tumours. They state, "Carcinoma of penis does not occur in people who have been circumcised in the first weeks of life and is rare in people who have been circumcised in childhood or in early puberty. Circumcision in adult life does not affect the frequency of the disease. Phimosis seems to be a predisposing factor. Penile cancer is frequent where personal hygiene is poor; it is rarer where bathrooms are plentiful. All this has been known for decades." Much the same ideas are contained in Sir Ernest Kennaway's⁵ recent paper in the *British Journal of Cancer*, where he writes, "The failure of the operation deferred until the fourteenth year to give the protection given by it when carried out on the eighth day suggests that the train of events leading to the malignant growth is set going early in life, and that removal of the cause does not then avert the development of cancer at a much later age. Other forms of cancer are perhaps due to factors acting in youth." The inference is that smegma in the first few years of life brings about irreversible changes in the tissues of the penis.

Fishman *et al.*,⁶ at the United States National Cancer Institute, had some years ago investigated the effect of human smegma on the vaginas of 20 young mice, but obtained only negative results. Plaut and Kohn-Speyer used smegma from horses because cancer of the penis is common in that animal and because of the advantage of appreciable quantities being available. The substance was applied every two or three weeks to 400 mice (Paris R.3 strain); 190 had smegma injected into a skin tunnel the walls of which consisted of skin and panniculus carnosus, 120 had subcutaneous injections, and 88 had the suspension of the unsaponifiable fraction of the smegma painted into the tunnel or on the skin surface. About 40% of the skin tunnels broke down, and in those cases the substance was injected subcutaneously. No tumours appeared in the 120 mice receiving only subcutaneous injections of horse smegma. In the 190 in which the substance was put in the skin tunnel, five tumours developed at the site—three papillary warts and two malignant tumours. In the 88 which had smegma painted into the tunnel or on the skin surface, one wart and two malignant tumours appeared. The malignant tumours consisted of two hornifying squamous-cell carcinomas with metastases, one undifferentiated skin carcinoma, and 1 spindle-cell sarcoma with metastases. The latent periods were very short—36, 82, 122, and 247 days for the warts, 130 for the sarcoma, 220 and 423 for the two carcinomas. Control mice were tested with cerumen instead of smegma,

since, unlike the penis, the auditory meatus is very rarely the site of cancer. No tumours developed in these mice.

There is therefore evidence that smegma is a weak carcinogen, and the proposition might be put forward, No prepuce, no smegma; no smegma, no cancer. Such an over-simplification obviously invites criticism. First, absence of prepuce probably induces changes in the exposed surfaces. Thus Dean,⁷ quoted in the paper by Sir Ernest Kennaway, writes, "There must be some reason why circumcision in infancy immunizes against cancer of the penis while circumcision later in life does not. It may be that when an infant is circumcised and the glans is no longer protected by the prepuce, a denser, thicker epidermis develops, which is resistant to the formation of cancer by chronic irritation. When circumcision is performed in later years the glans may have lost its ability to produce a resistant covering, and although there is no longer irritation from retained secretions, the glans remains relatively sensitive to the contacts of everyday life." Secondly, the smegma was obtained from one site in one species and tested at another site in another species. The ideal test for the carcinogenicity of horse smegma would have been to apply it continuously to the penes of circumcised horses. Thirdly, the carcinogenic activity of the material is no higher than that of a number of other fatty substances of biological origin, which now include the unsaponifiable fractions of liver, lung, kidney, muscle, and spleen—from cancerous and non-cancerous subjects, including the liver of still-born infants—either extract of mouse mammae, unsaponifiable fraction of cow's cream and milk, some vegetable and animal oils, oestrogens, and some substances found in commercial cholesterol (prepared from cattle brain and spinal cord).

The investigation of carcinogens obtained from tissues has certain peculiar difficulties. Because of the small percentage of positive results large numbers of experimental animals must be used. Again, the nature of the responsible compounds in the complex mixtures of substances remains unknown. As an illustration of this problem, Plaut and Kohn-Speyer point out that the unsaponifiable fraction of the smegma (6%) was about as active as whole smegma. To account for this it becomes necessary to suppose that removal of 94% of the material causes no change in its carcinogenic potency.

The appearance of 8 tumours (4 of them malignant) in 400 experimental mice would represent a very low potency for a synthetic carcinogen; it would be low even for some carcinogens from tissues. For example, Schabad's⁸ best preparation (benzol extract of human cancer liver) produced 4 tumours in 179 mice (subcutaneous injection). Steiner⁹ with an unsaponifiable fraction of human liver from cancerous or non-cancerous subjects obtained 12 tumours in 56 mice, but in later experiments reported 5 in 63, 12 in 456, and 16 in 440 mice. In his most recent paper Steiner⁷ describes an unsaponifiable fraction from the livers of non-cancerous patients which was highly active—27 sarcomas produced in 46 mice. The fraction from the livers of still-born infants showed considerable potency. Des Ligneris¹⁰ applied the unsaponifiable fraction of the livers of South African Bantus to the skin of mice, and numerous skin tumours developed.

Hieger,⁹ working on liver and other tissues from cancerous and non-cancerous human subjects, obtained 11 tumours in 28 mice by subcutaneous injection of the unsaponifiable fractions, and then 5 tumours in 30 mice. Other results he reported¹⁰ in later experiments were 3 tumours in 31

move, 2 in 10, and 3 in 25; and in a large series of about 300 mice injected with commercial cholesterol 6% developed tumours—all transplantable sarcomas. Thus it is obvious that the weakly carcinogenic activity of smegma is shared by numerous other fatty substances of biological origin.

HEALTH CENTRES FOR LONDON

The London County Council received from its Health Committee on May 11 proposals for carrying out the Council's duties under the section of the National Health Service Act relating to health centres. It was stated that these were the first of a series of proposals to enable the Council to develop health centres over the whole of the county. It is not possible at present to undertake much new building, and measures must be limited to ensuring that existing general medical and dental services which might otherwise cease at the appointed day can continue. The Council plans to build one specially designed health centre and to provide nine other centres by converting existing clinics or other suitable buildings; it will also acquire buildings for general medical and dental practitioners urgently needing facilities for group practice.

Subject to the agreement of the North-Eastern Metropolitan Regional Hospital Board and the Executive Council, the L.C.C. proposes to erect on its Woodberry Down estate at Stoke Newington a health centre providing six doctors' suites and two dentists' suites for the general medical and dental services; antenatal, post-natal, and child-welfare clinics; a school treatment centre; accommodation for health education; a foot clinic; and facilities for these services, including a clinical side room. It will be equipped, maintained, and staffed to the satisfaction of the Minister, and so far as general medical and dental services are concerned a professional committee will be appointed and charges made to doctors and dentists for the use of the centre on agreed terms. The area to be served has an estimated population of 10,500, but when the Woodberry Down estate is completed some 6,000 persons will be added. People living outside the prescribed area may also attend the centre. The estimated number of potential patients by mid-1950 will be 1,100 children aged 0 to 4, 1,700 children aged 5 to 14, and 12,200 adults—more when the Woodberry Down estate is finished.

The Council intends to provide ultimately a comprehensive health centre for each area having a population of approximately 20,000, so sited that no residents need travel more than about a mile from their homes to it. The county of London will be divided into 162 health service areas each of which will require a comprehensive health centre, with, in addition, some subcentres in certain special areas.

MICROKYMATOTHERAPY

High-frequency radiations with frequencies in the region of 3,000 megacycles and wavelengths measured in centimetres were the subject of much pre-war research, but it was their value in war that led to the development of microkymatotherapy of their practical application. A preliminary report by Krusen¹ and his colleagues on the possible use of high-frequency radiations with a wavelength of 10 cm. to produce therapeutic heat omits little of the history of the radiation in an account of their development. It is stated that the 10-cm. radiations, with a wavelength of 10 cm., can be focused, but the apparatus by which they can be focused can generate only a power

too low for therapeutic application. By 1939 research workers had raised the wattage of magnetron tubes from two or three to several hundred watts, "but suddenly a such tubes became mysteriously unavailable." This puzzled the American workers, who were not aware that such tubes had become a top-secret device employed in radar. Actually much Anglo-American work was proceeding on the multicavity magnetron tube, and by 1946 it was possible to obtain such a tube with a peak output of 400 watts. Work on the medical application of microwaves could therefore be resumed.

Microwaves have important optical properties and are transported along hollow tubes (wave guides) or coaxial cables. They can thus be "beamed." The first experimental medical work was done on dogs, and the problem of measuring the temperature of the tissues had to be solved. Thermocouples cannot be used during exposure to microwaves, so they had to be inserted before and after exposure. They showed that tissues could be heated by microwaves, and that by increasing output the temperature could be raised almost to any desired level. With a 75-milliampere plate current and a director at 5 cm. distance the skin temperature could be raised by between 3° and 5° C. (5.4° and 9° F.). Closer application of the director did not seem to affect the temperature level, and there seemed to be no appreciable difference in the temperature levels to which skin, subcutaneous tissue, and muscle were raised. Superficial tissues cooled more rapidly than deep, and cooling was more rapid in intact animals than in those that had been anaesthetized. By means of an ingenious flowmeter the rate of blood flow in the femoral veins of the experimental animals was measured, and it was found that this was always increased by more than 100% when the limb was exposed to the radiations.

It appears then that use of microwaves marks a definite advance in the therapeutic application of heat. Much more accurate localization may be possible than at present, and the use of cross beams converging at a given spot must be considered. To describe this new form of physical medicine American workers have coined the word "microkymatotherapy," because so far as plain English went with the use of ever shorter wavelengths they had "run out of diminutives."

RISKS OF DICOUMAROL THERAPY

Thrombosis of the leg veins, with the pulmonary emboli which may follow, was shown by Belt¹ to be as frequent a cause of morbidity and death in medical wards as in surgical. The introduction by Crafoord² of heparin as a prophylactic against thrombosis led to a considerable reduction of thrombo-embolic complications in surgery. The cost of heparin, however, still remains almost prohibitive, and supplies are certainly nothing like adequate to allow its general use in the prophylaxis and treatment of leg vein thrombosis. For this reason other anticoagulants are being sought, and dicoumarol, which has the advantage that it can be given by mouth, is now being widely used. Dicoumarol prolongs the prothrombin time, and, though it takes about two days for this effect to develop, the first 48 hours can be conveniently covered by heparin.

One of the most important indications for treatment with anticoagulants is coronary thrombosis. If the blood can be prevented from clotting, the thrombosis may remain limited, intracardiac thrombi may not form, and pulmonary emboli, which frequently occur during the period when these patients are confined to bed, may be avoided. Glueck

² *Acta chir. scand.*, 1937, 79, 407.

³ *Amer. Heart J.*, 1948, 35, 269.

⁴ *Schweiz. med. Wschr.*, 1947, 77, 911.

and his colleagues³ recently reported that in 44 control patients with coronary thrombosis thrombo-embolic complications occurred in 12, while in 44 treated with anticoagulants only 3 developed these complications. The mortality of the control group was 45%, while in those treated with anticoagulants it was 20%. Though these figures may not satisfy statistical demands, it is only by the accumulation of the results of careful clinical studies that final decisions will be reached on this important problem.

The mechanism by which dicoumarol interferes with the clotting process depends on its action in preventing prothrombin formation by the liver. The drug can only be given safely in hospital, as the margin between an effective therapeutic dose and a toxic dose is very narrow indeed. Furthermore, there is no easy way of standardizing dosage in any individual patient, and daily estimations of prothrombin time are necessary. There can be no relaxation of this precaution. Patients taking 200 mg. daily may retain a satisfactorily prolonged prothrombin time for ten days or a fortnight, and suddenly, without alteration of dosage, it is found that the prothrombin time has reached the danger level. Alternatively, in spite of keeping to the same dose, the prothrombin time may suddenly fall for no apparent reason, with the possible appearance of further thrombosis.

A recent report from Zurich by Koller and Pedrazzini⁴ emphasizes the danger of uncontrolled dicoumarol treatment. A patient who had received 0.3 g. of dicoumarol daily for 14 days developed epistaxis, gross haematuria, and blood in the stools. Subcutaneous and subconjunctival haemorrhages, together with other purpuric manifestations such as positive capillary resistance test and failure of clot retraction, were also present. In spite of the administration of a vitamin K preparation no change took place in prothrombin time, and it was only after a week, during which several blood transfusions were given, that the patient ultimately recovered. Liver function tests were mostly negative during this period. This report is a useful reminder of the necessity for the strictest control of anti-coagulant therapy. Fatalities are otherwise likely to occur, and the Zurich patient was fortunate to recover. Though dicoumarol seems to have earned its place in therapy at the moment, it is sincerely to be hoped that a safer anti-coagulant will be found before long.

HEAT AND HUMIDITY IN OPERATING THEATRES

In a recent issue of the *Journal* Wynne¹ discussed the difficulties associated with heat and humidity in operating theatres, and propounded a simple formula for the calculation of atmospheric dryness. He referred to the sling, or whirling, hygrometer, which is used in America as the instrument of choice for scientific accuracy, and said that in England the usual open-air method is to expose wet- and dry-bulb thermometers in a Stevenson screen, while in-doors the thermometers are simply hung in a room in comparative calm. His formula is based on the assumption that the wet-bulb thermometer is suspended in calm air. More recently Bell and Weir² have produced nomograms by means of which the relative humidity and the saturation deficit can be estimated readily from readings of the dry- and wet-bulb thermometers. These nomograms are suitable for use only when the wet-bulb temperature is that recorded by a thermometer suspended in calm air.

The speed of the air current passing over the bulb of a wet-bulb thermometer has a considerable effect on the temperature recorded by the thermometer, and when observations are made in a situation where the air speed varies the suspended type of hygrometer is a notoriously unreliable instrument. In calm air the wet-bulb becomes invested by a film of air which is more highly charged with water vapour than is the general atmosphere, and the wet-bulb temperature then recorded is erroneously high. However, if the instrument is so modified that air at a definite velocity is drawn past the thermometer bulbs it can be made to give reasonably precise readings. Satisfactorily ventilated thermometers are of two main types—the Assmann hygrometer, which needs no manipulation, and the whirling or sling hygrometer (or psychrometer). The nomograms of Bell and Weir are not suitable for a ventilated thermometer, but appropriate nomograms of similar construction could readily be drawn. There are available various psychrometric charts from which any desired measure of atmospheric humidity can be determined when the readings of a ventilated hygrometer are known. One such chart is depicted in the *M.R.C. War Memorandum No. 17*, and the supplement includes a reproduction on a large scale so as to facilitate accurate reading.

The authors referred to have been concerned with the humidity of the atmosphere, but the wet-bulb temperature is itself of considerable physiological significance. The interpretation in the light of recent physiological researches of hygrometric observations made in operating theatres must necessarily depend on the accuracy of the methods of measurement employed. Wynne emphasized the importance of the hazards to the patient of either hot and moist or cold atmospheres, and mentioned the risk of explosions due to high static electrical potentials in very dry atmospheres. He reported one instance in which a patient suffered adverse effects when the theatre temperature reached 81° F. (27.2° C.) and the air was very moist. In the *Annual Guide of the American Society of Heating and Ventilating Engineers* (1943) it is remarked that, while the conditions most comfortable for the operator are not identical with those most suitable for the patient, a compromise is usually not difficult to obtain with a relative humidity of 55 to 60% at temperatures between 72° and 80° F. (22.2 and 26.6° C.) (effective temperatures of 68° to 74° F.: 20° to 23.3° C.). In a study of the air-conditioning requirements of an operating room and recovery ward, Houghton and Cook³ found that effective temperatures of 68° to 70° F. (20° to 21.1° C.) not only provided comfort for the operating-room workers but apparently prevented exhaustion of the patient. Charts for the estimation of effective temperatures are also included in *M.R.C. War Memorandum No. 17*, but it is worth noting here that in calm air effective temperatures of 68° to 70° F. represent dry-bulb temperatures of 71.5° to 74° F. (21.9 to 23.3° C.) at 60% relative humidity, and temperatures of one degree higher when the relative humidity is only 50%.

The accommodation at Cambridge for the Annual Meeting of the B.M.A. is limited. In order that the arrangements may run smoothly we would ask those who intend being present to notify the Executive Officer as soon as possible. The form for doing so appeared in the *Supplements* of April 24, May 8, and May 15.

The next session of the General Medical Council will open on Tuesday, May 25, at 2 p.m., when the President, Sir Herbert Lightfoot Eason, will take the chair.

THE WORKING OF A HEARING-AID CLINIC

BY

R. SCOTT STEVENSON, M.D., F.R.C.S.Ed.

Surgeon, Metropolitan Ear, Nose and Throat Hospital

The earliest hearing-aid was probably the hand held behind the ear, and ear trumpets and tubes go back at least 250 years. Non-electric aids, such as ear trumpets and auricles, magnify only to a slight extent—about 15 decibels—but this can be surprisingly helpful, especially to an elderly deaf person afraid of the mechanics of an electric aid. The first electric hearing-aid, which was in essentials a portable telephone, was made in 1898 in America by the Dictagraph Company; this was a micro-telephone type of aid which worked from a single low-tension battery and generally had a carbon granule microphone with a hard or soft carbon diaphragm. The micro-telephone apparatus was quite convenient to carry about, but amplification was confined to the lower notes, and so it was useful only to cases of conductive ("middle-ear") deafness and not to cases of perceptive ("nerve") deafness. In 1934 a new phase in the development of hearing-aids began with the invention in Britain (the Americans copied the idea later) of the radio-valve amplifier, using the 18-mm. type of valve. These instruments, although fairly large—rather like an old-fashioned box camera—were much more efficient than the micro-telephone type, as they could reproduce sounds over a wide frequency range. The year 1938 saw the development of the first real pocket valve-amplifier hearing-aid, employing a fairly large high-tension battery and the usual type of low-tension battery, which had to be carried in separate pockets or in a lady's handbag. During the war of 1939-45 there was a rapid development of new electrical equipment for military purposes, particularly miniature 10-mm. radio valves (used in certain types of fuses) and much smaller batteries with longer life. These lent themselves to incorporation in hearing-aids, which could therefore be made much smaller and yet give the same maximum efficiency. It was at this time that the American hearing-aid manufacturers overtook the British ones, as they were not subject to the same restrictions; but since the war British hearing-aids have recovered the lost ground, and in some cases surpass their American counterparts.

In this country, until quite recent years, the position regarding hearing-aids was a reproach to the medical profession, who were content in cases of intractable deafness to allow a deaf patient to go to one commercial firm after another until he found—or was persuaded that he had found—an aid that appeared to help his hearing. In 1929 the National Institute for the Deaf stepped in to help the deaf by drawing up an approved list of dealers in hearing-aids, who (with a few notorious exceptions) signed an agreement not to canvass, not to publish extravagant and misleading advertisements, to inform a client when no aid appeared likely to help, and to allow a reasonable home trial for a small fee. The Institute was not allowed by law to circulate a black list, nor could its approval of dealers' ethical methods cover approval of the particular hearing-aids which they sold, but it did what it could. In 1930 it set up a research committee in association with the London School of Hygiene and Tropical Medicine, and the late H. M. Wharry carried out investigations at University College Hospital on the value of the micro-telephone hearing-aids then available, employing the 4A gramophone audiometer. Mr. Wharry's preliminary report in 1932 was not followed up after his untimely death, though Dr. G. P. Crowden and the late Dr. Phyllis Tooke Kerridge did some valuable work with deaf school-children and the Medical Research Council published a report on the use of hearing-aids by Dr. and Mrs. Ewing and Mr. T. S. Littler. In 1937 the National Institute for the Deaf stimulated a new advance. At that time the only modern audiometers being used to help in the prescription of hearing-aids were in the hands of commercial firms, and to avoid this a well-wisher offered to present one to the Institute to set up a hearing-aid advice department. It was pointed out, however, by the Institute's Medical Committee that before being tested with an audiometer or trying a hearing-aid a deaf person should

have his ears properly examined, for the deafness might be due to wax or suppuration or be relieved by Eustachian catheterization or other means, and that the suggested clinic should therefore be associated with a hospital.

An Important Service to the Deaf

The Metropolitan Ear, Nose and Throat Hospital started its Hearing-aid Clinic in the spring of 1937 in conjunction with one of the afternoon out-patient clinics. It was soon found to take up an inordinate amount of time, for the hearing-aid cases required special testing of hearing and the careful fitting of instruments, and for this reason it would probably have been dropped altogether but for the enthusiasm of the then almoner (now secretary), Miss Warshaw, who saw in a hearing-aid clinic a means of carrying out an important service to many deaf patients whom the otologists were inclined to dismiss as incurable. Even during the war years the Hearing-aid Clinic never stopped, although the hospital was bombed and its out-patient department was moved temporarily, first to Watford and then to new quarters at Granville Place, W.I. At this period the patients were first examined at the daily out-patient clinics by the honorary aural surgeon in charge, and when a hearing-aid seemed indicated audiometric tests were done by the almoner and suitable hearing-aids tried and fitted by her. For a time an assistant from a reputable firm of hearing-aid dealers came one evening a week to fit hearing-aids to referred patients; but experience proved that this was not a good method of getting an unbiased choice of hearing-aid, and it came to an end after a few months. At the beginning of September, 1945, when the hospital resumed its normal peacetime activities, the Hearing-aid Clinic was reorganized, with a staff of one full-time audiometrician and one trainee.

The Hearing-aid Clinic, which at present occupies four rooms, works to an appointment system, and is open every day from 9.30 a.m. to 5 p.m. (often later), except on Saturdays, when its hours are 9.30 a.m. to 12 noon. Every patient is first interviewed by the almoner and then examined by one of the aural surgeons in his out-patient clinic (unless he brings a recent letter from an otologist), who carries out an investigation of the history of the deafness and the reasons why a hearing-aid is wanted, as well as a routine examination of the ears, nose, and throat, tuning-fork tests, voice and whisper tests, Eustachian catheterization if necessary, and arranges such pathological or x-ray examinations as may be indicated. A deaf patient considered likely to benefit from a hearing-aid is then sent on to the Hearing-aid Clinic, where an audiometric examination is made, one copy of an audiogram being filed and one put with the out-patient case-notes. The rooms used for audiometric examination are ordinarily quiet comfortable rooms with furniture in them, not a specially built bare "silence-room": this is emphasized because we have heard an otologist say that he was going to start a hearing-aid clinic when he could get a silence-room built—which may take a very long time in these days. A deafness research clinic has different objectives and requires different equipment from a hospital hearing-aid clinic—a "silence-room" is necessary at the former but not at the latter.

Training the Audiometrician

At the Metropolitan Ear, Nose and Throat Hospital we have trained our own audiometricians, and are training others. No one can do good audiometry without guidance, without experience, and without knowledge of the methods available and the problems to be met. Hallpike (1948) has said (in an *obiter dictum* at an otological discussion) that "it is not really necessary to create another branch of technical auxiliaries." On the other hand, the American otologists Lederer and Hardy (1946) wrote: "It is not good enough to assign the job [of audiometry] part-time to a medical secretary who knows no more about audiometric testing than to snap switches and turn dials. Every aspect of the work with the hard of hearing suggests the need for respecting the psycho-social behaviour of the patient, and good audiometry is no exception." And Carhart (1946) said that the interviewer who decides whether the patient is to be fitted with an air- or a bone-conduction instrument, and on which ear the aid is to be worn, "obviously must have wide training and experience." Our audiometricians are not taken from the nursing staff; it seems to us a waste, at a time when

there is a shortage of nurses, to assign a trained nurse to this work. They are well-educated (high-school standard) young women drawn to social work, who might, for example, have become hospital almoners or medical secretaries. The course has a duration of six months, and comprises training in making correct and reliable audiometric charts of the various types of deafness, in testing patients for suitability for hearing-aids, and in selecting the appropriate aid for the individual case; it includes attendance at the hospital speech therapy and lip-reading clinics. At the end of their course the students have to pass an examination in the basic principles of anatomy and physiology of the ear, the basic principles of acoustics, the physics of audiometers and hearing-aids and their mechanisms, the psychology of the deaf, the handling of deaf-mute children, and the principles of lip-reading; they must also have an adequate knowledge of medical terminology and of professional ethical conduct. It is stated on the certificate given after examination that the holder is not entitled to examine patients or fit hearing-aids except under the direction of a registered medical practitioner, and that any breach of this condition is contrary to the interests of the patient and will render the certificate liable to cancellation.

Testing by the Audiometer

Hallowell Davis, Stevens, *et al.* (1947) have stated, after extensive investigations, that it is a fallacy that hearing-aids, like eye-glasses, must be "fitted" to the detailed idiosyncrasies of the individual impairment, and that an audiogram does not help greatly in fitting a hearing-aid. We have found, as a result of our experience in the Hearing-aid Clinic, that when an audiometric examination shows a hearing loss of 30 to 40 decibels in the speech frequencies a hearing-aid becomes necessary, and a suitable aid should give a gain in speech reception of at least 40 decibels. The instruments of two years ago were not of much help with a loss of 50 decibels, but those of to-day are helpful in many cases with a loss of as much as 70 decibels. Hallowell Davis and Stevens believe that most deaf patients hear best with an aid that amplifies all the frequencies uniformly, and this conclusion is supported by the M.R.C. Committee on Electro-Acoustics, which found that the best results could be obtained with a uniform amplification of the sounds in the range of speech. We defer to these opinions, but we must say that the experience at our Hearing-aid Clinic is that in most cases either high or low frequencies have to be emphasized in the hearing-aids. It is noticeable that "nerve"-deafness patients, with a higher frequency loss, are often helped—in a way that would have been considered impossible a year or two ago—by modern aids that appear to boost the higher frequencies actually by cutting down the lower frequencies. Many cases that an otologist has diagnosed as "middle-ear" deafness because bone conduction for the 256 and 512 tuning-forks was markedly better than air conduction have been shown by the audiometer to be cases of "nerve" deafness, with marked hearing loss for the higher frequencies. Bone conduction, with masking, must always be tested with the audiometer as well as air conduction, and helps in differential diagnosis.

The audiometer is essential, not so much for the actual "fitting" of the hearing-aid, but as part of the clinical examination that gives the picture, as nearly complete as possible, of a case of deafness, and as a permanent record for later comparison. Audiometers must be regularly tested and correctly calibrated—we have four audiometers in our clinic, and one of them is usually away for calibration, retesting, or repair. In addition there is a gramophone audiometer for testing groups of children, and we have on order a "peep-show" (Dix and Hallpike, 1947, 1948) for testing the hearing of very young children.

There are now three full-time audiometricians in the Hearing-aid Clinic, and each tests the hearing and fits the patient with a suitable hearing-aid. The clinic has a "library" of hearing-aids, only those manufactured by firms on the "approved list" of the National Institute for the Deaf being included, though new instruments not on the list are tried out. The firms invited freely lend their latest instruments (we have had only one refusal, and one firm was excluded because it would not allow a discount for hospital patients), which comprise Acousticon, Amplivox, Auratone, Belclere, Bonochord, Compensator,

Multitone, and Sonotone, several types of each being available. In addition there is a large variety of non-electrical instruments, comprising single and double auricles, ear-shells, speaking-tubes, and banjo-type, bell-type, cup-type, swan-type, and expandible trumpets.

The Fitting of Hearing-aids

The patient who comes to a hearing-aid clinic wants, above all, to hear and understand the human voice, other sounds, such as music or the door-bell or the general sounds around, are less important to the average deaf person. Speech should be intelligible but not uncomfortably loud, and if possible should have a "natural" quality. The frequencies necessary for the comprehension of speech range between about 250 and 4,000 cycles per second. It is not necessary for a hearing-aid, therefore, to provide for all the audible frequencies, but if they are cut off at 3,000 some consonants, such as *f*, *s*, and *t*, are inaudible and speech is difficult to understand: when cut off at 2,000 speech is incomprehensible. In fitting hearing-aids the audiometrician speaks sentences to the patient containing first words that are low in pitch (e.g., *wall*, *hole*), then of medium pitch (e.g., *king*, *name*), and lastly high in pitch (e.g., *bit*, *face*). Words are also spoken faintly and then loudly, and the volume control of the instrument is checked. When the patient has decided which instrument to take on trial, the audiometrician, by causing extraneous noises, shows him how to concentrate on hearing what he wants to hear and to ignore the extraneous sounds. He is told to wear the instrument at first only at home and not in the street, to get accustomed first to the new sounds of familiar persons and surroundings, and only gradually to be introduced to stranger and unexpected sounds.

All existing modern hearing-aids are basically similar: there are innumerable minor differences, but the electrical instruments used in the Hearing-aid Clinic all consist essentially of a microphone, an amplifier, and a receiver. Engineering compromises are unavoidable in the design and construction of a hearing-aid, for the objectives of low cost and light weight are definitely opposed to the objectives of high fidelity, high amplification, adequate power output, and long battery life. In the United States and Canada no deaf person now thinks of using any receiver other than a midget telephone receiver fitted snugly into the external auditory meatus with a moulded plastic insert: our experience is that the disk-type of receiver, with head-band, is more efficient than the moulded insert receiver, but because it is uglier and more uncomfortable nearly all the patients at the clinic demand the plastic moulded insert, and the audiometricians are instructed in making individual moulds. Bone-conduction receivers, which were popular with carbon microphone aids, have only a limited use with the valve type of instrument: this is because they give poor reproduction of sounds above 2,000 cycles per second and because a relatively higher electrical power is needed as compared with the ordinary receiver. Nevertheless a small number of deaf patients with good bone conduction do find that a suitable bone-conduction receiver (there are three types) applied to the mastoid gives a better result than a disk or insert receiver.

Secondary considerations are important to the patient: the instrument should not be too expensive either in initial outlay or in upkeep; it should be small and light in weight, easy to manipulate, comfortable to wear; and repair and replacement service and a supply of batteries should be reasonably available. Although hearing-aids are basically similar in their mechanism, it is surprising how a patient will pick out one particular instrument as much more suitable to him than any of the others—sometimes because of qualities that appear bad to the audiometrician, such as a raucous tone that "gets through" to him, or because an instrument is the most expensive (not the cheapest), or even because he prefers the colour of the case. The patient's work has to be taken into consideration—professional, clerical, manual, home duties, and also whether a portable aid is really necessary. The audiometricians are instructed, while giving every help in choosing the most suitable aid, to leave the final choice to the patient; it is bad psychology to appear to force any particular aid on the patient even when it seems to the audiometrician the most suitable; and, in addition, comfort in hearing is as important in making a choice as is clearness.

THE WORKING OF A HEARING-AID CLINIC

BY

R. SCOTT STEVENSON, M.D., F.R.C.S.Ed.

Surgeon, Metropolitan Ear, Nose and Throat Hospital

The earliest hearing-aid was probably the hand held behind the ear, and ear trumpets and tubes go back at least 250 years. Non-electric aids, such as ear trumpets and auricles, magnify only to a slight extent—about 15 decibels—but this can be surprisingly helpful, especially to an elderly deaf person afraid of the mechanics of an electric aid. The first electric hearing-aid, which was in essentials a portable telephone, was made in 1898 in America by the Dictagraph Company; this was a micro-telephone type of aid which worked from a single low-tension battery and generally had a carbon granule microphone with a hard or soft carbon diaphragm. The micro-telephone apparatus was quite convenient to carry about, but amplification was confined to the lower notes, and so it was useful only to cases of conductive ("middle-ear") deafness and not to cases of perceptive ("nerve") deafness. In 1934 a new phase in the development of hearing-aids began with the invention in Britain (the Americans copied the idea later) of the radio-valve amplifier, using the 18-mm. type of valve. These instruments, although fairly large—rather like an old-fashioned box camera—were much more efficient than the micro-telephone type, as they could reproduce sounds over a wide frequency range. The year 1938 saw the development of the first real pocket valve-amplifier hearing-aid, employing a fairly large high-tension battery and the usual type of low-tension battery, which had to be carried in separate pockets or in a lady's handbag. During the war of 1939–45 there was a rapid development of new electrical equipment for military purposes, particularly miniature 10-mm. radio valves (used in certain types of fuses) and much smaller batteries with longer life. These lent themselves to incorporation in hearing-aids, which could therefore be made much smaller and yet give the same maximum efficiency. It was at this time that the American hearing-aid manufacturers overtook the British ones, as they were not subject to the same restrictions; but since the war British hearing-aids have recovered the lost ground, and in some cases surpass their American counterparts.

In this country, until quite recent years, the position regarding hearing-aids was a reproach to the medical profession, who were content in cases of intractable deafness to allow a deaf patient to go to one commercial firm after another until he found—or was persuaded that he had found—an aid that appeared to help his hearing. In 1929 the National Institute for the Deaf stepped in to help the deaf by drawing up an approved list of dealers in hearing-aids, who (with a few notorious exceptions) signed an agreement not to canvass, not to publish extravagant and misleading advertisements, to inform a client when no aid appeared likely to help, and to allow a reasonable home trial for a small fee. The Institute was not allowed by law to circulate a black list, nor could its approval of dealers' ethical methods cover approval of the particular hearing-aids which they sold, but it did what it could. In 1930 it set up a research committee in association with the London School of Hygiene and Tropical Medicine, and the late H. M. Wharry carried out investigations at University College Hospital on the value of the micro-telephone hearing-aids then available, employing the 4A gramophone audiometer. Mr. Wharry's preliminary report in 1932 was not followed up after his untimely death, though Dr. G. P. Crowden and the late Dr. Phyllis Tookey Kerridge did some valuable work with deaf school-children and the Medical Research Council published a report on the use of hearing-aids by Dr. and Mrs. Ewing and Mr. T. S. Littler. In 1937 the National Institute for the Deaf stimulated a new advance. At that time the only modern audiometers being used to help in the prescription of hearing-aids were in the hands of commercial firms, and to avoid this a well-wisher offered to present one to the Institute to set up a hearing-aid advice department. It was pointed out, however, by the Institute's Medical Committee that before being tested with an audiometer or trying a hearing-aid a deaf person should

have his ears properly examined, for the deafness might be due to wax or suppurative or be relieved by Eustachian catheterization or other means, and that the suggested clinic should therefore be associated with a hospital.

An Important Service to the Deaf

The Metropolitan Ear, Nose and Throat Hospital started its Hearing-aid Clinic in the spring of 1937 in conjunction with one of the afternoon out-patient clinics. It was soon found that to take up an inordinate amount of time, for the hearing-aid case required special testing of hearing and the careful fitting of instruments, and for this reason it would probably have been dropped altogether but for the enthusiasm of the then almoner (now secretary), Miss Warshaw, who saw in a hearing-aid clinic a means of carrying out an important service to many deaf patients whom the otologists were inclined to dismiss as incurable. Even during the war years the Hearing-aid Clinic continued, although the hospital was bombed and its out-patient department was moved temporarily, first to Watford and then to new quarters at Granville Place, W.1. At this period deaf patients were first examined at the daily out-patient clinic by the honorary aural surgeon in charge, and when a hearing-aid seemed indicated audiometric tests were done by the almoner and suitable hearing-aids tried and fitted by her. For a long time an assistant from a reputable firm of hearing-aid dealers came in the evening a week to fit hearing-aids to referred patients; this experience proved that this was not a good method of providing an unbiased choice of hearing-aid, and it came to an end a few months. At the beginning of September, 1945, when the hospital resumed its normal peacetime activities, the Hearing-aid Clinic was reorganized, with a staff of one full-time audiometrician and one trainee.

The Hearing-aid Clinic, which at present occupies two rooms, works to an appointment system, and is open every day from 9.30 a.m. to 5 p.m. (often later), except on Saturdays, when its hours are 9.30 a.m. to 12 noon. Every patient is first viewed by the almoner and then examined by one of the otologists in his out-patient clinic (unless he brings a recent letter from an otologist), who carries out an investigation of the history of the deafness and the reasons why a hearing-aid is wanted, as well as a routine examination of the ears, nose and throat, tuning-fork tests, voice and whisper tests, Eustachian catheterization if necessary, and arranges such pathological x-ray examinations as may be indicated. A deaf patient is considered likely to benefit from a hearing-aid is then sent to the Hearing-aid Clinic, where an audiometric examination is made, one copy of an audiogram being filed and one put in the out-patient case-notes. The rooms used for audiometric examination are ordinarily quiet comfortable rooms with comfortable furniture in them, not a specially built "silence-room"; this is emphasized because we have heard an otologist say that he was going to start a hearing-aid clinic when he could get a silence-room built—which may take a very long time in the days. A deafness research clinic has different objectives; it requires different equipment from a hospital hearing-aid clinic, and a "silence-room" is necessary at the former but not at the latter.

Training the Audiometrician

At the Metropolitan Ear, Nose and Throat Hospital we have trained our own audiometricians, and are training others; one can do good audiometry without guidance, without experience, and without knowledge of the methods available to meet the problems to be met. Hallpike (1948) has said (in an *editum* at an otological discussion) that "it is not necessary to create another branch of technical audiology." On the other hand, the American otologists Lederer and Hall (1946) wrote: "It is not good enough to assign the job of audiometry part-time to a medical secretary who knows more about audiometric testing than to snap switches and for dials. Every aspect of the work with the hard of hearing suggests the need for respecting the psycho-social behaviour of the patient, and good audiometry is no exception." And Goss (1946) said that the interviewer who decides whether the patient is to be fitted with an air- or a bone-conduction instrument must be on which ear the aid is to be worn, "obviously must have training and experience." Our audiometricians are not taken from the nursing staff; it seems to us a waste, at a time

There is a shortage of nurses, to assign a trained nurse to this work. They are well-educated (high-school standard) young men drawn to social work, who might, for example, have some hospital almoners or medical secretaries. The course is a duration of six months, and comprises training in making correct and reliable audiometric charts of the various types of deafness, in testing patients for suitability for hearing-aids, and selecting the appropriate aid for the individual case; it includes attendance at the hospital speech therapy and lip-reading clinics. At the end of their course the students have to pass an examination in the basic principles of anatomy and physiology of the ear, the basic principles of acoustics, the principles of audiometers and hearing-aids and their mechanisms, the psychology of the deaf, the handling of deaf-mute children, the principles of lip-reading; they must also have an adequate knowledge of medical terminology and of professional ethical conduct. It is stated on the certificate given after examination that the holder is not entitled to examine patients for hearing-aids except under the direction of a registered medical practitioner, and that any breach of this condition is contrary to the interests of the patient and will render the certificate liable to cancellation.

Testing by the Audiometer

Hallowell Davis, Stevens, *et al.* (1947) have stated, after extensive investigations, that it is a fallacy that hearing-aids, like eyeglasses, must be "fitted" to the detailed idiosyncrasies of the individual impairment, and that an audiogram does not help at all in fitting a hearing-aid. We have found, as a result of our experience in the Hearing-aid Clinic, that when an audiometric examination shows a hearing loss of 30 to 40 decibels the speech frequencies a hearing-aid becomes necessary, and a suitable aid should give a gain in speech reception of at least 10 decibels. The instruments of two years ago were not of much use with a loss of 50 decibels, but those of to-day are helpful in many cases with a loss of as much as 70 decibels. Hallowell Davis and Stevens believe that most deaf patients hear best with an aid that amplifies all the frequencies uniformly, and this conclusion is supported by the M.R.C. Committee on Electroacoustics, which found that the best results could be obtained with a uniform amplification of the sounds in the range of speech. We defer to these opinions, but we must say that the experience at our Hearing-aid Clinic is that in most cases either the low or low frequencies have to be emphasized in the hearing-aid. It is noticeable that "nerve" deafness patients, with a moderate frequency loss, are often helped—in a way that would have been considered impossible a year or two ago—by modern hearing-aids that appear to boost the higher frequencies actually by fitting down the lower frequencies. Many cases that an otologist has diagnosed as "middle-ear" deafness because bone conduction for the 256 and 512 tuning-forks was markedly better than air conduction have been shown by the audiometer to be cases of "nerve" deafness, with marked hearing loss for higher frequencies. Bone conduction, with masking, must always be tested with the audiometer as well as air conduction, to help in differential diagnosis.

The audiometer is essential, not so much for the actual "fitting" of the hearing-aid, but as part of the clinical examination that gives the picture, as nearly complete as possible, of a patient's deafness, and as a permanent record for later comparison. Audiometers must be regularly tested and correctly calibrated—we have four audiometers in our clinic, and one of them is usually away for calibration, retesting, or repair. In addition there is a gramophone audiometer for testing groups of children, and we have on order a "peep-show" (Dix and Lipike, 1947, 1948) for testing the hearing of very young children.

There are now three full-time audiometricians in the Hearing-aid Clinic, and each tests the hearing and fits the patient with a suitable hearing-aid. The clinic has a "library" of hearing-aids, only those manufactured by firms on the "approved list" of the National Institute for the Deaf being included, though instruments not on the list are tried out. The firms invited to lend their latest instruments (we have had only one refusal, and one firm was excluded because it would not allow discount for hospital patients), which comprise Acousticon, Plivox, Auratone, Belclere, Bonochord, Compensator,

Multitone, and Sonotone, several types of each being available. In addition there is a large variety of non-electrical instruments, comprising single and double auricles, ear-shells, speaking-tubes, and banjo-type, bell-type, cup-type, swan-type, and expandable trumpets.

The Fitting of Hearing-aids

The patient who comes to a hearing-aid clinic wants, above all, to hear and understand the human voice; other sounds, such as music or the door-bell or the general sounds around, are less important to the average deaf person. Speech should be intelligible but not uncomfortably loud, and if possible should have a "natural" quality. The frequencies necessary for the comprehension of speech range between about 250 and 4,000 cycles per second. It is not necessary for a hearing-aid, therefore, to provide for all the audible frequencies, but if they are cut off at 3,000 some consonants, such as f, s, and t, are inaudible and speech is difficult to understand; when cut off at 2,000 speech is incomprehensible. In fitting hearing-aids the audiometrician speaks sentences to the patient containing first words that are low in pitch (e.g., wall, hole), then of medium pitch (e.g., king, name), and lastly high in pitch (e.g., bit, face). Words are also spoken faintly and then loudly, and the volume control of the instrument is checked. When the patient has decided which instrument to take on trial, the audiometrician, by causing extraneous noises, shows him how to concentrate on hearing what he wants to hear and to ignore the extraneous sounds. He is told to wear the instrument at first only at home and not in the street, to get accustomed first to the new sounds of familiar persons and surroundings, and only gradually to be introduced to stranger and unexpected sounds.

All existing modern hearing-aids are basically similar: there are innumerable minor differences, but the electrical instruments used in the Hearing-aid Clinic all consist essentially of a microphone, an amplifier, and a receiver. Engineering compromises are unavoidable in the design and construction of a hearing-aid, for the objectives of low cost and light weight are definitely opposed to the objectives of high fidelity, high amplification, adequate power output, and long battery life. In the United States and Canada no deaf person now thinks of using any receiver other than a midge telephone receiver fitted snugly into the external auditory meatus with a moulded plastic insert; our experience is that the disk-type of receiver, with head-band, is more efficient than the moulded insert receiver, but because it is uglier and more uncomfortable nearly all the patients at the clinic demand the plastic moulded insert, and the audiometricians are instructed in making individual moulds. Bone-conduction receivers, which were popular with carbon microphone aids, have only a limited use with the valve type of instrument; this is because they give poor reproduction of sounds above 2,000 cycles per second and because a relatively higher electrical power is needed as compared with the ordinary receiver. Nevertheless a small number of deaf patients with good bone conduction do find that a suitable bone-conduction receiver (there are three types) applied to the mastoid gives a better result than a disk or insert receiver.

Secondary considerations are important to the patient: the instrument should not be too expensive either in initial outlay or in upkeep; it should be small and light in weight, easy to manipulate, comfortable to wear; and repair and replacement service and a supply of batteries should be reasonably available. Although hearing-aids are basically similar in their mechanism, it is surprising how a patient will pick out one particular instrument as much more suitable to him than any of the others—sometimes because of qualities that appear bad to the audiometrician, such as a raucous tone that "gets through" to him, or because an instrument is the most expensive (not the cheapest), or even because he prefers the colour of the case. The patient's work has to be taken into consideration—professional, clerical, manual, home duties, and also whether a portable aid is really necessary. The audiometricians are instructed, while giving every help in choosing the most suitable aid, to leave the final choice to the patient; it is bad psychology to appear to force any particular aid on the patient even when it seems to the audiometrician the most suitable; and, in addition, comfort in hearing is as important in making a choice as is clearness.

A "difficult" patient may be referred to the medical psychologist associated with the Hearing-aid Clinic, Dr. Hilda Weber, who also instructs and advises the audiometricians on the psychology of the deaf and on the proper approach to their problems; sometimes the psychiatrist on the staff of the hospital, Dr. Kenneth Hazell, is called in to help. It is a rule that all patients who have been fitted with a hearing-aid must be referred to the teacher of lip-reading or speech-reading on the staff of the hospital, Miss Sylvian Martin, who has two clinics weekly. Speech correction and lip-reading are essential auxiliaries to the hearing-aid—60% of words may be understood by the use of a hearing-aid alone, but up to 90% by combined hearing-aid and lip-reading. Older persons unfortunately find lip-reading more difficult to learn than do young people.

Grants to the Deaf

When an electrical aid is required and has been chosen the patient is carefully instructed in how to wear and how to use it; the type is then approved by the aural surgeon in charge of the case and the patient takes a note to the manufacturer, who supplies the specified aid on a week's (sometimes a fortnight's) trial. At the end of a week the patient returns and reports progress to the aural surgeon, consults the audiometrician about any difficulties in using the instrument, and then sees the almoner again with regard to its purchase. The manufacturers on the hospital list all allow a discount of 25% (15% on certain instruments), and the almoner assists the patient with advice about obtaining grants-in-aid. Some Approved Societies give grants, as do the Hospital Saving Association and other voluntary contributory schemes. The Royal Surgical Aid Society may give a grant, but "letters" from subscribers have to be obtained; the Hospital Saturday Fund, Church funds, and the Gentlemen's Aid Society may help with grants; and some commercial firms or employees' organizations make grants from their benevolent funds—the railway-workers and printers' organizations have been particularly good. Some City companies, such as the Vintners, Curriers, and Clothworkers, have been helpful in giving grants in certain cases, and the Goldsmiths Company in particular has helped to provide many hearing-aids for Londoners through its fund, administered by the National Institute for the Deaf. Deaf-blind patients get help through the blind organizations; children suitable for hearing-aids can obtain them free through the educational authorities; and the Assistance Board gives grants in special cases. It is claimed by the hospital almoner that no patient requiring a hearing-aid has ever had to go without it on financial grounds. When the instrument has been purchased the patient is given careful instructions on how to look after it. All patients are seen again at the clinic after three months, and retested with the audiometer; in almost every case the hearing has been found to have improved owing to the stimulative effect of a suitable aid and to the improvement in the psychological outlook.

Some Results

The time taken up by each patient at the Hearing-aid Clinic, including preliminary examination, audiometric examination, and fitting with a hearing-aid, varies from one to two hours—certainly no patient ever takes less than an hour altogether. In spite of this, and of the care taken in fitting aids, an unexpectedly high proportion of the hearing-aids are returned after the week's trial. It was primarily to help reduce this wastage that a medical psychologist was attached to the Hearing-aid Clinic.

The reasons that are given for returning a hearing-aid vary: "Found it a nuisance"—did not switch it on and off as instructed; "Dared not wear it at work—would get the sack"; "Did not want to let everyone know I was deaf"—as if people wouldn't know already; "Too old to cope"; "Could not hear when several people were talking"—needed education in listening; "Could not hear in church or at the pictures"—difficulties of acoustics explained; "Felt everyone was looking at me"—further lesson given in wearing modern aid; "Anything on or in the ears worried me"; "Too dear to buy"; "Too expensive to run"—in spite of help from the almoner; "Difficulty in obtaining suitable batteries"—this should have been only temporary; "Didn't think it worth the money"; "Wanted

rather to have an operation to cure my deafness"; "Prefer to wait for the Government aid"—especially during the past six months.

In 1946, 355 electrical hearing-aids were recommended at the Clinic, and 170 of them were returned; 120 non-electrical aids were recommended, and 62 of them were returned. In 1947, 776 electrical aids were recommended, and 256 of them were returned; 53 non-electrical aids were recommended, and 28 of them were returned. It will be noted that the proportion of non-electrical to electrical aids has greatly diminished in the past year, and the reason for this seems to be the improvements in the valve-amplifier aids, which have made them more suitable for cases of "nerve" deafness. It has been suggested that the chief reason for the return of hearing-aids is their expense, and that the advent of the Government free hearing-aid will wipe out this wastage; but an endeavour has been made to show that the financial factor has not been an important difficulty in regard to the provision of hearing-aids in suitable cases, and when the Government aid is available lack of choice may well be an additional factor in patients returning (or giving up using) hearing-aids. This wastage at our Hearing-aid Clinic has given us a certain amount of sympathy with the commercial dealers, who have argued that insistence on a preliminary trial has increased their costs and immobilized a large proportion of their stock of instruments.

There is no doubt that more time should be spent—if only it could be spared—on training patients to get accustomed to the selected hearing-aid and in listening to different sounds (songs, orchestral music, voices) and to different individuals and groups. We envy the United States War Veterans' Organization when we read that five weeks are spent in residence at Deshon, Philadelphia, and similar centres in selecting hearing-aids and training the patients to use them properly—with the result that only 5% of the instruments are returned.

Conclusions

The modern valve-amplifier hearing-aid has improved greatly in the past two years, and is able to help many cases of perceptive ("nerve") deafness as well as most cases of conductive ("middle-ear") deafness. It will probably be a still better instrument within the next five years.

The provision of a suitable hearing-aid is only part of the rehabilitation of a deaf person, and adequate training in its proper use is necessary. Training in lip-reading should always be combined with the use of a hearing-aid, and "difficult" deaf patients are often helped by a medical psychologist. Every hospital ear, nose, and throat department should be associated with a hearing-aid clinic—of which at present there are only 19 in Britain, and some of these consist in a hearing-aid dealer making periodical visits.

The Ministry of Labour and National Service, in conjunction with the Ministry of Health, is sending three mobile nursing exhibition vans on tour in different parts of the country to encourage recruitment to the nursing and midwifery professions. The vans are fitted out partly as an exhibition with photographs, a nursing panorama, a skylight view into a model operating theatre, and a display of surgical instruments, and partly as an interviewing room in which persons interested—young people, parents, teachers, and others—may ask about pre-nursing courses, opportunities for training, salaries, or other points about nursing and midwifery. A technical nursing officer of the Ministry of Labour will be available to give advice and information.

MEDICAL PHOTOGRAPHY

The first exhibition of medical photography to be arranged by the Medical Group of the Royal Photographic Society can be seen at the Royal Society of Medicine, 1, Wimpole Street, W.1, from Monday, May 24, to Saturday, May 29. There are many outstanding photographs and coloured transparencies. The photographic departments of most of the larger hospitals are well represented. We reproduce on this page two of a series of three photographs taken by Miss Margaret Crossley in the department of orthopaedic surgery of the Wingfield-Morris Hospital at Oxford. Several photographs have been taken with infra-red rays and show the superficial veins, notably in lactation and in cases in which a collateral circulation is evident. Many of the photographs are of rare or unusual cases, and there are some excellent photomicrographs.

A dramatic picture of a case of anorexia nervosa is reminiscent of the Belsen "horror" photographs. Unusual items are the self-portrait of a radiologist; a picture of a celluloid cast of the blood supply to the stomach; and an enormous enlargement of a glomerulus. Perhaps the dermatologists and the ophthalmologists have contributed most to this exhibition, but there are a number of entries from gynaecological and dental departments, and almost every specialty is represented.

Medical Group

Previously medical photography had been treated as part of the province of the Scientific and Technical Group of the R.P.S., but in April, 1946, with the guidance of Mrs. Rosalind Maingot, F.R.P.S., the Medical Group was formed under the chairmanship of Sir Cecil Wakeley. The Group now has 153 members. For the present exhibition, which it is hoped will become an annual event, some 300 prints and 150 transparencies, the majority in colour, were submitted by 85 photographers, either hospital departments or individuals. Of these entries 150 prints, 75 transparencies, and 6 films and filmstrips were accepted by the judges.

The Medical Group responsible for this exhibition is very active and has already contributed a number of papers to the proceedings of the

Royal Photographic Society. It also circulates among its members two portfolios which allow all of them to see the best current work in different branches of medical photography. The interest taken in this subject has recently been revealed in our correspondence columns, where a sharp division of opinion has been reflected. Dr. Frangcon Roberts in an article in our opening pages (March 13) criticized the expansion of departments of medical photography. He has since been taken to task by some of our correspondents and supported by others. The debate continues in this issue at page 1001.

The photographs on exhibition at the Royal Society of Medicine will probably help to confirm both parties to the argument in their original views. There are some sets of photographs and transparencies of undoubted value for teaching purposes. There are also a large number of rarities which are photographically impressive, of interest to those originally concerned with the case in question, but of little or no general interest. At the same time the exhibition will allow medical men to see what assistance may be expected from the medical photographer in keeping records and in teaching.

Visual methods of instruction are being increasingly applied, and however views may differ on the limitations of medical photography this exhibition will at least serve to show the high standards which have been achieved technically. Noteworthy in this connexion are some of the photographs showing diseases of the eye.

September Exhibition

It should perhaps be recorded here too that the Royal Photographic Society will hold its 93rd Annual Exhibition at the Society's house at 16, Prince's Gate, S.W.7, during September and October. In the second part of the exhibition, which will be devoted to scientific, technical, nature, and record photography, the Medical Group will again have an opportunity to compare its own standards with those achieved by photographers working with subjects in the allied sciences. There will be a medical and surgical section, and medical and industrial radiographs will be judged separately. The scientific section of this annual exhibition always endeavours to show exhibits which illustrate the use of photography for obtaining information which cannot be secured in any other way.

WORLD HEALTH ORGANIZATION

WORK OF THE INTERIM COMMISSION

The International Health Conference held in July, 1946, adopted a constitution for the World Health Organization which provided that it would come into force once 26 members of the United Nations had become parties to it. On April 7, with the ratification of its constitution by Mexico and Byelorussia, the World Health Organization came into being as one of the Specialized Agencies of the United Nations.

The first World Health Assembly will be convened at the Palais des Nations, Geneva, on June 24 and is expected to continue to the end of July. Delegations will be present from at least 35 nations—27 U.N. members and 8 non-members. The United States and France are the two major powers which have not yet ratified the W.H.O. constitution. In the case of the United States the Bill for ratification passed the Senate last year and had been unanimously approved in the House Foreign Relations Committee. However, the House of Representatives Rules Committee tabled the Bill by a vote of five to two. The United States has shown only slight hesitation in voting funds to the eight other specialized agencies of the United Nations. Unfortunately this Bill, which it was hoped to pass during the last Congressional session, was frozen out by more immediate problems.

W.H.O. has brought under one control the functions shared previously by the Office International d'Hygiène Publique in Paris, the Health Organization of the League of Nations in Geneva, and the Health Division of Unrra. Since July, 1946, all essential international duties have been carried out by the Interim Commission of W.H.O. The Interim Commission has managed the fund for the award of fellowships to medical specialists from war-devastated countries. It has embarked on a large public health and training programme in China. It also co-operated successfully with the Egyptian public health authorities in dealing with the recent cholera epidemic. A great deal has been written about this epidemic, but there is one point that has rarely been mentioned. Our American correspondent writes:

"When the news of the epidemic first reached this country it appeared to stimulate the business rather than the humanitarian instincts of certain of the pharmaceutical companies, and the price of anti-cholera vaccine rose to 8 cents per ml. By dint of investigations and discussions the secretariat of the Interim Commission succeeded in completing arrangements with two drug firms for the manufacture of the vaccine at a price of 2 cents per ml. They very wisely gave full publicity to these more public-spirited manufacturers and it is hoped that this will act as a stimulus to straight dealing when next the need may arise."

Expert Committee on Tuberculosis

At the fifth session of the Interim Commission held in Geneva early this year the first report of the Expert Committee on Tuberculosis was accepted for submission to the World Health Assembly. The Expert Committee, which consisted of only three members, called attention to the fact that the fight against infectious disease was a task for the whole of humanity. Fortunate and relatively healthy nations must come to the aid of stricken nations in order to help eradicate tuberculosis. The Expert Committee listed eleven principal "techniques" for tuberculosis control: (1) the determination of the extent of the problem in each country; (2) the recruitment and training of professional personnel; (3) the provision of physical facilities, supplies, and equipment; (4) health education; (5) the demonstration of practical activities in the field by well-trained teams; (6) the distribution of financial grants when necessary; (7) the development of uniform procedures in tuberculosis research; (8) the co-operation of all international organizations concerned with tuberculosis control; (9) the eradication of tuberculosis in cattle; (10) the study of the legal and epidemiological aspects of the problem of tuberculosis; (11) the review every year by the World Health Organization of the efficacy of its programme for the control of tuberculosis.

The Expert Committee on Tuberculosis is only one of eleven similar committees set up by the Commission. The others are concerned with international epidemic control; revision of the

pilgrimage clauses of the international sanitary conventions quarantine; yellow-fever; habit-forming drugs; the sixth biennial revision of the international lists of diseases and causes of death; biological standardization; unification of pharmacopoeias; malaria; and venereal diseases.

World Health Assembly

The first World Health Assembly will receive the reports of these expert committees. It is expected that the Interim Commission will be dissolved soon after the adjournment of the Assembly. The agenda also includes the selection of a Director-General for W.H.O. and of a permanent site for the organization. A number of nations have already declared a preference for a permanent site. Geneva heads the list, with New York, Paris, Washington, and London as successive choices. In the House of Commons recently Mr. Bevan said that he was considering whether it would be possible to offer accommodation in London for the 1949 World Health Assembly. The proposed budget for 1949 amounts to \$6,387,995, which is more than twice the Interim Commission's budget for the first year of its work. The largest single sum, \$1,071,690, is allotted for fellowships, medical literature, teaching equipment, and emergency medical supplies.

One of the most important functions of W.H.O.—"medical co-operation with accredited governmental and non-governmental agencies"—is the subject of a recommendation of the fifth session of the Interim Commission. The recommendation was that the Assembly should adopt the draft agreements drawn up by the Interim Commission with several U.N. Specialized Agencies. "These agreements provide that the W.H.O. shall serve in an advisory capacity in the fields of public health and medicine with the following organizations: the International Civil Service Advisory Board, the U.N. Social Commission, the U.N. Scientific Conference for the Conservation and Utilization of Resources, International Labor Organization, Unesco, and Food and Agricultural Organization."

In this connexion the apparently long delay in obtaining sufficient ratifications may prove to have been of value. Other specialized agencies of the United Nations achieved a permanent position soon after its creation. There has been a growing body of criticism of some of these agencies on the grounds that they have sponsored projects which are unnecessary, unripe, or outside the real sphere of their activity. These errors were easy enough to fall into in the early enthusiasms of the infant United Nations, and a much more deliberate start may well have saved the first World Health Assembly from such pitfalls.

Meanwhile the Interim Commission in its closing stages can look back on a record of progressive work unspoiled by lack of international co-operation. When the Commission is dissolved by the World Health Assembly its chairman, Dr. Andrija Stampar, of Yugoslavia. Dr. Brock Chisholm, of Canada, the executive secretary, and their colleagues will be able to congratulate themselves on achieving over a period of nearly two years an international outlook and a degree of international co-operation and amity which might well be copied by other delegates of the United Nations in the political field.

NEW LOOK FOR HEALTH

At the Health of the People Exhibition, which was opened in London last week by Princess Elizabeth, the Central Office of Information and the Ministry of Health have attempted to give health a new look. Their efforts have met with considerable success, for the exhibits are well designed and attractively displayed. The purpose of the exhibition is to mark the centenary of the first Public Health Act of 1848, and to record the progress that has been made since then in improving public health, leading up to the inauguration of the National Health Service later this year. In one section the spectator is confronted with a series of questions about the new health service, and is invited to press buttons to learn the answers. One of the questions is "Will Doctors Be Civil Servants?" When the appropriate button was pressed a light flashed in an empty panel—plainly a case in which the quiz-master was baffled by his own question.

At exhibitions of this kind there is a danger of so overwhelming the spectators with a mass of pictures, models, and graphs that they go away with only a confused impression of what it was all about. Skilful display counteracts this to some extent, but it was significant that on the day the exhibition opened the greatest interest was being shown in laboratory work actually being carried out in full view of spectators. In fact, there was a queue of people waiting to have their blood groups tested. The romance of Science obviously does not extend to graphs and statistics, nor to water supplies and drains.

"Visual Aids" are now very much in the fashion among educationists, and the use of films and film-strips in popular health education is certain to increase. At the Health of the People Exhibition some of the latest educational health films are being shown. One of these, "Modern Guide to Health," is a cartoon produced by John Halas and Joy Batchelor, who have been highly praised for their work by the professional film critics. Simple common-sense advice about posture, exercise, clothes, and sleep is given an original twist by the freshness of the drawings and the cleverness of technique. The same technique makes the cartoon, "Your Very Good Health," well worth seeing, but this film is frank propaganda for the National Health Service Act, and so far from being instructional might even be considered misleading.

In the future much more thought, time, and money will be spent on health education than hitherto. Prof. Andrew Topping has recently said, "I am firmly convinced that education is the greatest single factor in achieving results in the health field . . . in the promotion of health we must have a prepared and receptive community." The speed with which knowledge about health and disease can be applied depends largely on the state of public opinion. With the Health of the People Exhibition the Ministry of Health has set a useful example to local health authorities, which after July 5 will be responsible for health education.

TRAVELLING FELLOWSHIPS IN MEDICINE

The Medical Research Council invites applications for the following Travelling Fellowships for the academic year 1948-9

Rockefeller Medical Fellowships

These Fellowships are provided from a fund with which the Council has been entrusted by the Rockefeller Foundation of New York. They are intended for graduates resident in this country who have had some training in research work in clinical medicine or surgery, or in some other branch of medical science, and who are likely to profit by a period of work at a centre in the United States or elsewhere abroad, before taking up positions for higher teaching or research in the United Kingdom. The stipend will ordinarily be at the rate of £525 per annum for a single Fellow, and of £800 per annum for a married Fellow. Travelling expenses and some other allowances will be paid in addition.

Dorothy Temple Cross Research Fellowships in Tuberculosis

These Fellowships are awarded by the Council from a special endowment of which it is the trustee.

The object of the Fellowships, as defined in the trust deed, is to give special opportunities for study or research to suitably qualified British subjects of either sex "intending to devote themselves to advancement by teaching or research of curative or preventive treatment of tuberculosis in all or any of its forms." The Fellowships will, as a rule, be awarded to candidates who wish to make their studies or inquiries elsewhere than in the United Kingdom. They will ordinarily be awarded for one academic year, and provide for the payment of stipend, together with an allowance for travelling and incidental expenses. The stipend will ordinarily be at the rate of £525 per annum for a single Fellow, and of £800 per annum for a married Fellow.

Completed applications for Fellowships of either type must be lodged with the Council by June 1. Further particulars and forms of application are obtainable from the secretary, Medical Research Council, 38, Old Queen Street, Westminster, London, W.1.

IMPERIAL CANCER RESEARCH FUND ANNUAL REPORT
